Thermo-electric Couples.—76. A separation of the electricities similar in character to that which we have just described as accomplished by chemical force is brought about by the direct action of heat on dissimilar conductors in contact. Thus, if we have a series of bars of antimony and bismuth united at their alternate ends, as shown in Fig. 21, and heat one side, DC, while the other, AB, is either exposed to the air or otherwise cooled, a separation of the electric fluids will be effected, and one extremity of the series will acquire a positive, while the other gains a negative, charge. As can easily be imagined, the electro-motive force is very feeble in this case, and thus very delicate instruments are required to recognize the effect. Moreover, the internal resistance of the system will be very small, since it consists entirely of conductors, and we must therefore employ low-resistance circuits for the measuring instruments to be used with it.

Fig. 21.

By uniting a large number of minute bars of antimony and bismuth in the manner indicated into a square prism, a "thermo-electric pile" is formed. This is generally enclosed in a brass case, provided with hollow conical reflectors, such as *a*, for its ends, and supported on a stand. It then forms with an astatic galvanometer (see § 73) the most delicate means we possess of indicating changes in temperature, the change in temperature being estimated from the effect of the electric action which it produces. Many experiments have been made by Becquerel, Bunsen, Marcus, and others on the development of this source of electric force. (See "Phil. Mag.," 1865, vol. xxix., pp. 159, 406; also vol. xxx., p. 77; likewise "Jour. of Fr. Inst.," vol. xlix., p. 420.) Much also has been done in this line by Moses G. Farmer of Boston.

Fig. 22.

Animal Electricity.—77. It has been shown that pieces of muscular tissue from animals recently killed will develop actions identical in character with those produced by chemical or heat forces, as before described, and moreover that certain animals, notably the torpedo and electric eel, have the power of giving at pleasure heavy discharges by means of a special apparatus which resembles in its structure a series of galvanic couples. (*Faraday, Phil. Trans.*, 1839, part i., p. 1.) It has been shown by Matteucci that in living animals an electric current is perpetually circulating between the internal and external portions of the muscles. This no doubt derives its source from the chemical actions constantly in progress in connection with the vital processes.

Other, and what may be called secondary, methods of exciting galvanic electricity, such as that of induction from another current or from a magnet, will be given farther on, after the subject of induction itself has been discussed.

Mechanical Effects of Electric Currents.—78. Our consideration of that form of electrical development known as galvanic or dynamic has led us thus far rather to notice its close resemblance to, or rather general identity with, the statical or frictional form of the same action: but while there is this exceedingly close relation between the two—while, in fact, they only differ in the degree of some of their conditions—it is yet true that this amount of difference is great enough to warrant the division of the subject which exists, and to make two classes of phenomena, which, while equally *existing* in both, are each of them pre eminent in one of the two subjects, and practically inappreciable in the other.

These marked differences are in the quantity and intensity of the electric disturbances. In the case of the simple galvanic couple already described the amount of the fluids which can be separated is immense, but the separating force is so deficient in intensity that it can accomplish no condensation of the fluid in an insulated conductor, but can only do its work when the fluids are allowed to flow round and unite as fast as they are developed. It is like

one of the great wheels used in draining the Haarlem Lake, which by rotating in a broad canal pushed the whole body of water along, and raised it only a few inches. It could produce the current as of a river through a nearly level channel, but for producing a "head" of water or high pressure it was all but powerless.

On the other hand, the frictional methods of excitement give us a means of packing away or condensing the fluid to any extent, but are able to put but little in motion at a time. To carry out our former illustration, they might be compared to the pumps of hydrostatic presses, which can produce a tremendous "head" of water, but deliver only a few ounces at each stroke.

The great self-repellent force of each fluid makes the condensation of even a small amount into a limited space a work requiring great intensity of power, while the want of weight in the electric substance makes the movement of great quantities a matter dependent simply on what might be called frictional resistance (*i. e.* the obstacle offered by the transmitting material or conductor to their passage). It thus comes that while in statical electricity we have chiefly to do with what we may consider highly compressed fluids forcibly accumulated in different bodies, in dynamical electricity we have to consider the flow of large volumes of the same fluids but little compressed, and thus having little mutual repulsion or tendency to diverge. Thus, it comes that in the first case we can only have marked results as a rule from the properties these fluids possess when at rest. There will not be volume enough to produce any effect if let out as a current. It would be like letting out the water from a hydraulic press against a mill-wheel. And so, on the other hand, we must have a clear circuit and free passage for the fluids in order to obtain the dynamical phenomena. The quietly flowing river can swing round a hundred wheels, but would not push down a handful of earth that fenced it off from some child's excavation in its beach.

While, therefore, there *are* tension and accumulation and every effect resulting from the properties of the fluids when at rest, in dynamic electricity; we have to consider mainly the effects of currents flowing easily in closed circuits. According to our double-fluid theory, we know that if the positive fluid is moved into one body, the negative equally goes into the other, and that thus the flow of one in one direction will involve the flow of the other in the opposite. It therefore becomes an unnecessary repetition to go over each description a second time, simply reversing the order, and we therefore commonly confine our descriptions to the motions of the positive fluid, assuming that the negative follows the same track, "the other way round."

Attractions and Repulsions of Electric Currents.—79. The attraction for light bodies exhibited by those excited by friction evidently depends upon the accumulation of one or the other fluid in the excited body; but nothing like this can exist with a current, which being, as we have seen, duplex in its character (*i. e.* an equal flow of positive in one direction and negative in the other), can have no accumulation or charge of either fluid at any point. Thus, no phenomena of attraction and repulsion are to be expected from closed circuits upon light bodies.

We may, however, expect that two currents, or the conductors carrying two currents, should attract or repel each other, and that this attraction and repulsion should depend upon the relation of their directions. This is indeed found to be the case. If two currents flow in parallel wires in the same direction, the wires tend to approach; if the directions are opposite, they tend to recede. This fact may be illustrated in a variety of ways, but perhaps that which is at once the simplest and most striking is to have two pieces of wire bent so as each to form three sides of a square; then so to weight these by rods rigidly attached that they will stand on their ends. Four slight hollows containing mercury are then so arranged as to receive the ends of these wires when they stand close together and parallel. If, then, the mercury cups are so connected that a current from a battery will traverse the two wires successively in the same direction, they will be seen to approach; if in opposite directions, they will recede.

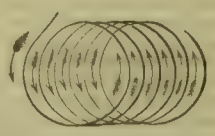
80. If straight conductors carrying currents are so placed as to form an angle with each other, they will attract if both currents go towards or from the apex of the angle, but will repel if one approaches and the other recedes. This is, however, a direct consequence of the former law. The action of a sinuous current is equal to that of a rectilinear one equal to its length in projection.

81. From the law of angular currents we easily derive the law regarding currents at right angles to each other—one in a fixed conductor and the other movable round an axis or in any direction parallel with itself. If the current in the movable conductor approaches the fixed one, then it will cause the movable conductor to advance in a line parallel to that of the fixed conductor, in a direction opposite to that of its current, and in the same direction as this current if the direction of the current in the movable wire be away from the fixed one. Consequently, a vertical rectangle or circle carrying a current will tend to assume a position parallel to a horizontal conductor, and so as to bring the horizontal currents of both into the same direction.

82. Again, as a direct consequence of the reactions of angular currents not in the same plane, we will see that a current in a wire occupying the relation of a radius to the line around which it is free to move will tend to perform a continuous rotation if acted upon by a current in a tangent or circumferential conductor in or parallel to its plane of motion. A current in a wire perpendicular to this same plane would be similarly affected.

Fig. 23.

Thus, if a current is made to pass up through a central column, and then divide in opposite directions through wires A B, then descending into a trough of mercury while another current or a continuation of the same passes through a surrounding ring of wire, EF, a continuous rotation will be maintained.



These are some of the results of the simple general law that currents in the same direction attract, and in opposite directions repel.

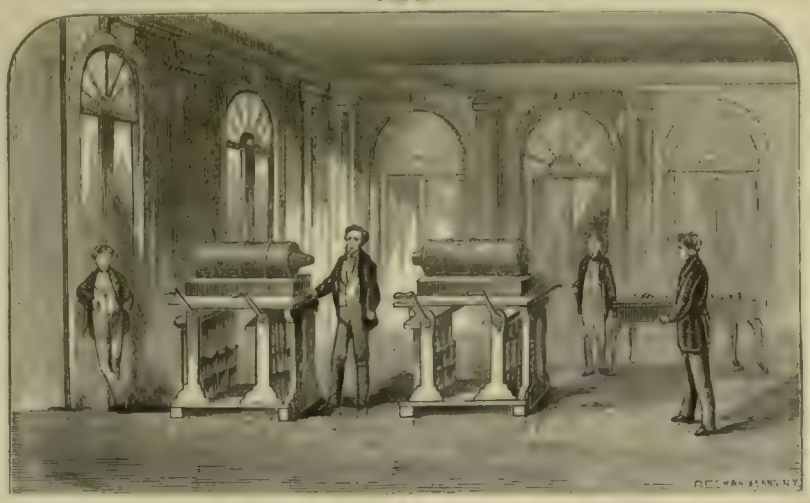
Relations between Magnets and Currents.—83. The theory of Ampère, fully explained in another place (see "Magnetism"), develops all the properties of magnets, from the assumption that they are equivalent to spirals carrying currents, or are made up of particles, each of which has in it a closed circuit, all moving in the same direction. (See Figs. 24 and 25.) From this it would naturally follow that mutual actions would exist between magnets and currents, such as might be derived from the elementary law and examples given above. Such is indeed the case. Moreover, the earth itself playing the part of a powerful magnet, we should expect certain relations to subsist between its directive force or polar action and the movements of free conductors carrying currents. These also we find.

Fig. 24.

Fig. 25.

84. Thus, we have, as perhaps first in importance, the fruitful fact discovered by Œrsted that a magnet tended to set itself at right angles to the line of a current, and reciprocally that a conductor carrying a current would set itself at right angles to a magnet. Regarding the magnet simply as a series of currents in planes perpendicular to its length, these actions are simply examples of the tendency of currents to get into parallel planes, resulting from the first simple law of their attraction and repulsion. For exactly similar reasons, free conductors carrying currents place themselves at right angles to the magnetic meridian.

85. The rotations of magnets around conductors and conductors around magnets, which flow from this same relation, are as numerous as their explanation, by reference to the above general considerations, is obvious. For an extended discussion of these the reader is referred to De la Rive's "Traité d'Électricité," tom. i., chap. 2.



86. A solenoid is a helix or spiral, with the wire of which it is formed returned along its axis. When therefore a current traverses it the longitudinal effect of the spiral is counterbalanced by that of the return wire, and it becomes in all respects equivalent to a series of equal and parallel circular currents. In fact, it fulfils exactly Ampère's description of a magnet. As might be expected, therefore, it behaves in all respects exactly like one.

Magnetization by Currents.—87. If a bar of soft iron is inserted in a solenoid, it is found to become powerfully magnetic as long as the wire is traversed by a current, the order of the poles being as follows: if the current passes round in the direction of the hands of a watch, the pole on the near side will be a south pole.

If in place of a solenoid, we surround the iron bar with a multiple coil of many layers of insulated wire, the current acting repeatedly will produce a greatly-increased effect. By this means magnets of the greatest power are produced. They are called, for distinction, electro-magnets, and, as has been already remarked, lose their power practically with the cessation of the current.

The largest and most efficient electro-magnet yet constructed is one built, after the designs prepared by Prof. A. M. Mayer and the present writer, by Mr. William Wallace of Ansonia, Conn., for the Stevens Institute of Technology. It weighs with its armatures about 1800 pounds, has cores of soft iron six inches in diameter and three feet three inches each in length, and surpasses any similar instrument in the intensity of its effects.

FIG. 25.

On the peculiar properties of the electro-magnet was founded the invention of the electro-magnetic telegraph. (See TELEGRAPH.)

88. The great power which an electro-magnet exerts on a body near it has led many to attempt the application of this as a motor in driving machinery. A consideration of the numerical results given at §§ 52 and 53, in connection with the explanation of the origin of the galvanic force, will, however, show us that zinc consumed in one of the forms of galvanic battery which does not involve the use of some other very expensive material will yield us but about one-tenth to one-sixteenth the force produced by coal in its combustion; and even if made perfectly available by some discovery not yet even hinted at, would be but one-fourth as effective as coal. The price of zinc is moreover at present about forty times that of coal. Our present steam-engines give us about five per cent., or one-twentieth, of the total force evolved by their fuel; so that with an absolutely perfect battery and electro-motor the economic relation would be eight times in favor of the steam-engine with such batteries as could be used—twenty and thirty-two times if the engine were absolutely perfect; but with the best form of engine yet devised it would be 100 to 160 times more expensive to obtain power by a galvanic motor than by a steam-engine.

Laws of Electro-Magnetism.—89. It has been shown by Lenz and Jacobi that with an uniform current—1st, Magnetism in any given bar is directly proportional to the number of coils which act upon it. 2d, The diameter of the coils has no effect, the greater length of the larger coil exactly compensating for its greater distance. 3d, The thickness of the wire has no effect, the condition first named of a constant current being maintained. Of course, with the same battery the amount of the current will be largely influenced by the size and consequent resistance of the wire. 4th, The strength of the magnetism is proportional to the quantity of the current. This and certain other relations, it will be readily seen, have a limit in the capacity of a bar of iron to receive a magnetic charge. 5th, The attractive power of the electro-magnet for a saturated steel bar varies with the inverse square of the distance, but for a bar of soft iron, where induction comes in, with some function approaching the inverse cube of the distance. 6th, The retentive power varies with the square of the charge or of the quantity of current. 7th, The amount of magnetism developed is largely influenced by the surface of the iron, though not depending only on that; so that a tube whose thickness is about one-sixth its diameter would be equivalent to a solid bar of the same diameter. 8th, The length of the bar has no effect on its magnetic force, beyond that of diminishing the interfering action of the opposite poles by separating them. 9th, The position of the bar in the helix, whether in or out of its axis, is immaterial.

An excellent research on several of these points, involving a very beautiful and accurate method for comparison of magnetic forces, was published by Prof. A. M. Mayer in the "Am. Jour. of Science" for Sept., 1870.

Electrolysis, or Chemical Action of an Electric Current.—90. As a chemical combination is on the one hand an effective source of the electric current, so on the other side this current may expend itself in reversing this action, or in decomposing such compounds as in their formation gave it birth. Thus, if the current from a series of galvanic elements be made to pass through a solution of sulphate of zinc, the oxide of zinc will be decomposed, metallic zinc appearing at one side, and oxygen gas being given off at the other. So with the sulphate of copper and other salts not too difficult to decompose; and in such cases it is found that if the conductor to which the oxygen goes is of a metal, such as copper, iron, zinc, etc., which can combine readily with that element, an oxide will be formed and dissolved by the liberated acid.

On this fact are founded the various processes of electro-plating, of electrotyping, and the like.

A conducting matrix or mould or object is suspended in a solution of the metal to be deposited, in connection with the zinc or negative pole of the battery, and a plate of the same metal is suspended in the same liquid and in connection with copper, carbon, or other positive pole of the battery. The metal is then deposited gradually on every portion of the mould or object, and may either be left there, as in plating, gilding, etc., or stripped off, as in electrotyping, where it becomes the cast or duplicate original which is to be used.

91. The firmer the union of the elements or compounds the more difficult it is to separate them. Thus, if such a salt as sulphate of soda is placed in solution between the poles of a moderate battery, we can readily separate the acid from the base, but not the elements of the base. For this a very powerful combination is required, such as was used by Davy when he first separated, and so discovered, the metallic elements of the alkalies and earths. The elements of water are not very difficult thus to dissociate, and this has been adopted as a convenient means for measuring the quantity of the current. By employing the most intense means at our command, we can even act upon the elementary gases, so as to effect a possible separation of these. (See OZONE.)

92. A fluid state, as might naturally be expected, allowing of motion among the particles, seems to be essential to electrolysis, and we obtain this either by solution or fusion where it does not exist already; and we find that in all cases the most electro-negative element or component of the compound collects on the zinc pole, and the more positive on the other.

TRANSFER OF DYNAMIC ELECTRICITY—*Conduction.*—93. Conduction in dynamic electricity resembles in all respects the same action in the statical condition of the fluids. It varies in the same way with different substances, but can be more readily studied and measured. Moreover, on account of the inappreciable "condensation" of a current, the conductor does not act mainly by its surface, but by its entire section. The following list will give some idea of the relation of a few substances in this respect.

Silver	100.
Copper, pure	99.9
" best commercial	85–95.
" ordinary "	40–70.
Brass	20.
Zinc	29.
Steel	about 16.

Iron	about 15.
German silver	12-16.
Lead	8.3
Platinum	6.9
Mercury	1.6
Pure graphite	0.069,3
Coke, or coal-gas graphite	0.038,6
Tellurium	0.000,77
Red phosphorus	0.000,001,23
Solution of sulphate of copper, saturated	0.000,000,005,4
Sulphuric acid and water, 1-11 vols.	0.000,000,088
Sulphate of zinc, saturated solution	0.000,000,005,7
" " " half saturated	0.000,000,007
" " " quarter "	0.000,000,005,4

From this table will be noticed the great effect which the presence of any impurity has upon the conducting power of a metal, and the very inferior conducting power of alloys as compared with their constituents.

Again, we see the vast difference between the conductivity of metals and that of non-metallic bodies and solutions, and that, moreover, in some solutions the conductivity reaches a maximum at a certain strength, and declines either by concentration or dilution.

94. It is observed, moreover, that in the case of metals the conductivity varies inversely with the temperature, while the non-metallic ones rise in conductivity as the temperature is elevated. Thus, in gutta-percha used to insulate cables for submarine telegraphy, the conductivity increases about thirty-six times in passing from 32° to 90° F. Glass at a red heat becomes a good conductor. The same general action takes place in liquids, conductivity increasing with temperature; and thus we find a moderate heat favorable to battery-action and to electrolysis.

95. Gases under ordinary circumstances are almost perfect insulators, but it has been shown by Andrews, Hankel, E. Becquerel, and Buff that some slight indications of conduction could be obtained, and Magnus found that hydrogen exceeded other gases in this respect. When intensely heated, however, as in certain spectrum or Geissler tubes, gases seem to conduct with a sensible facility; possibly also in the electric arc.

Heating and Luminous Effects.—96. When a galvanic current passes through a conductor, heat is developed to a degree varying with the amount of the current and the resistance of the wire. Other things being equal, an increase of resistance will diminish the amount of the current, but if we keep the current constant by adding to the electromotive forces urging the current, then we shall find the heat developed increase with the resistance. If the quantity of the current is increased, the heat will increase as the square of this quantity. In ordinary experiments it is more easy to increase the amount of the current transmitted by decreasing the length of the resistance, and thus obtaining a greater development of heat in a part of the line. Thus, if we have a platinum wire stretched between two rods or posts, and, connecting one of them with one pole of a powerful battery, draw the other terminal along the wire, beginning with the farther end, the heat in the wire will increase as the part through which the current passes decreases in length, until, if the battery is sufficiently powerful, the wire is at last even fused. Again, if a wire of some length is kept at a red heat by a battery, we may make one part glow much more brightly by cooling another with cold water. The reason is, that by cooling we increase the conducting power or diminish the resistance of that part, and so allow more current to be forced through the remaining portion. Many similar examples might be cited did space permit.

97. The interesting conclusion has been reached by Favre (*Comptes Rendus*, vol. lv., p. 56) that the total amount of heat generated by the solution of a given quantity of zinc in galvanic circuit is constant, being diminished in the battery as it is increased in the exterior circuit; and moreover that heat is lost when motion is produced just in the proportion that Joule's theory and equivalent would require.

98. From what has been said above, we see that if electric fluid could be forced in any amount through a non-conducting substance, very intense effects of heat and light ought to be produced. This is in fact observed in the case of the statical discharge in air, which affords us the most intense exhibition of these forces with which we are acquainted. With galvanic electricity it is, however, under ordinary conditions, impossible to obtain sufficient concentration to rupture the resistance of air. If, however, the poles of a powerful battery of, say, forty or fifty Grove or Bunsen elements are brought into contact, and then slightly separated, a bridge of particles torn off from the positive and hurled upon the negative pole is formed, and maintains the connection. Resistance enough, however, is offered to develop a light of the most dazzling brightness.

It is found most convenient to make the terminals in this case from a very dense and, in an ordinary sense, incombustible carbon or "coal-gas graphite" (such as is used for elements in the battery cells, except that a finer and purer preparation is here essential). Even this material is slowly dissipated in the intense heat of the electric arc, and various forms of self-adjusting regulators have therefore been devised by which the carbon points are made to approach each other as they are consumed.

99. If the lower carbon is hollowed into a cup, various substances, such as the metals and salts, can be placed in it, and converted into incandescent vapor by the action of the discharge. By this means the peculiar colored lights which they emit may be analyzed with a prism and projected as "spectra" on a screen with a very beautiful effect.

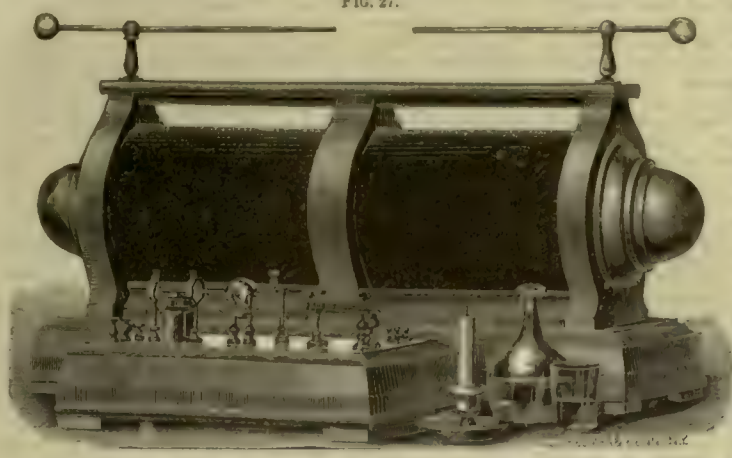
While, as we have already shown (§ 88), a galvanic current derived from chemical actions involving the use of zinc and other expensive materials is not at all able to compete with the coal-consuming engine as a source of mechanical power, yet by reversing the order of conversions and employing the cheap mechanical power of the steam-engine to develop a galvanic current (see § 104), and using this to produce light as above, something useful may be accomplished. In an interesting paper on the cost of the electric light (*Am. Jour. of Science*, 1868, vol. xlv., p. 113), Moses G. Farmer has shown that where a light of about 1000 candles was required it could in this way be produced at one-tenth the cost of the same amount of gas-light.

Galvanic or Dynamic Induction.—100. This action, whose theoretical explanation has defied the insight even of Faraday, is in its simplest form of exhibition as follows: Suppose that two wires are arranged side by side, but mutually insulated for some length, and that one of them is connected in closed circuit with a delicate galvanometer, while the other may be made at will the path of a current from a galvanic battery. If this connection is made, we will notice an instantaneous movement of the needle in the galvanometer, indicating a momentary current in the opposite direction to that of the battery. While this battery flows all is absolutely at rest, but the moment that an interruption occurs, another instantaneous current is shown by the galvanometer, but now in the same direction as the battery current followed. These momentary currents are called secondary or induced currents, and that producing them is called the "primary" current.

If the two wires, in place of being in parallel straight lines, had been wound each in a flat spiral, and these spirals had been in close proximity, the effect would have been the same. In this case, moreover, if instead of causing the primary current to start and stop, we allowed it to flow continuously, but brought the spirals quickly together and then as quickly separated them, the same induced currents would have been generated as before.

Bearing in mind, as has been already stated, that a magnet represents in all respects a spiral carrying a current, it is evident that the mutual approach and separation of magnets and helices should produce secondary currents in the latter, and so likewise the charging and discharging of electro-magnets in the presence of spirals or other conducting circuits.

101. Again, this "induced current" may be developed in the primary circuit or wire itself. It is then called the extra current. Also, as Prof. J. Henry has shown, the secondary current may in its turn be made to develop another, and this again a fourth, and so on to an indefinite limit.



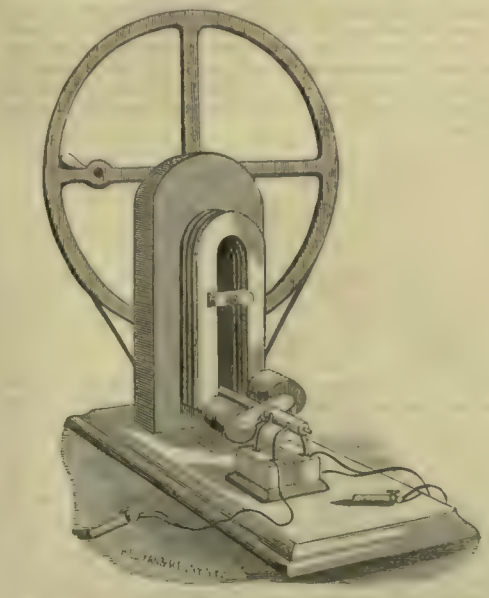
In addition to their great scientific interest, these actions above briefly noticed have developed two of the most remarkable instruments for the production of electric phenomena, the induction coil and the magneto-electric machine.

102. The induction coil consists of a thick wire wound into a spiral around a bundle of soft iron needles. This receives, through a "break-piece" or "interrupter," either automatic or moved by hand, a discontinuous current from a galvanic battery. Around this primary spiral, but most thoroughly insulated from it, even by a heavy glass jar, is another or secondary spiral of very fine wire and of great length. The terminals of this furnish the positive and negative fluids. To do away with the interfering action of the "extra current," a condenser is connected with the primary circuit at either side of the break-piece. This condenser is equivalent to a Leydon jar of great surface, and is made of tin-foil separated by oil-silk.

The battery connections being made, and the interrupter put in action, at each break of circuit flashes of electricity pass between the terminals with a length and brilliancy depending upon the size and perfection of the instrument. One of these coils, built for the present writer by Mr. E. S. Ritchie of Boston, to whom the instrument owes its efficient and practical development (*Jour. of the Franklin Institute*, vol. xl., p. 64), is shown in the accom-

panying cut. (See Fig. 27.) The outer or secondary coil of this instrument contains fifty miles of wire, .007 inch in diameter, covered with silk; the primary wire is 200 feet

FIG. 27.

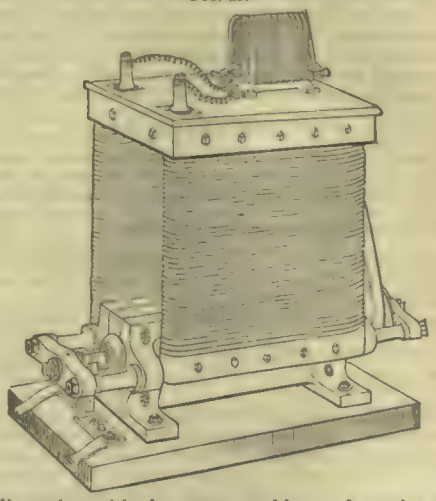


long and 0.1655, or about one-sixth of an inch, thick. The condenser contains 325 square feet of coated surface. With three cells of battery, each having in use, when freshly charged, not more than half a square foot of active surface, this instrument throws sparks in the air through a distance of twenty-one inches, and pierces solid blocks of glass three inches thick. When connected with a large Leyden jar the sound of its discharge is painful.

103. In addition to its numerous applications in scientific connections, this instrument has been used with great success as a means of lighting instantaneously the numerous gas-burners in public buildings, such as theatres. Many of these buildings in Boston, New York, and Philadelphia are so lit up. It is also employed in the Lenoir gas-engine to ignite the mixture of gas and air in the cylinder.

Magneto-Electric Machines.—104. If a coil of wire is rapidly caused to approach and recede from a permanent magnet, a series of induced currents will be developed in it. An easy way of securing this approach and withdrawal is to make several such coils rotate in front of large magnets in the manner shown in the cut. (See Fig. 28.) If bars of soft iron are fixed in the coils, they will receive and

FIG. 28.



lose their charge, and so greatly add to the effect. Thus, then, such a machine may be constructed, and by terminating the coils in plates on opposite sides of the axis, which thus will alternately touch springs resting against it on either side, we may correct the reversal of the currents, and get them from these springs in a constant direction. This machine has received a great number of modifications, of which the important ones are Siemen's armature and Wilde's application of cumulative action.

105. Siemen's armature consists of a small cylinder of iron having two deep grooves cut along its length on opposite sides. In these grooves the wire is wound, and by this means the whole piece can be placed between the poles of a series of horseshoe magnets, or otherwise in a very intense field of force. It is moreover in a form admirably adapted for rapid rotation.

106. Wilde was the first to apply the discovery that the current developed by one magneto-electric machine could charge electro-magnets with a far greater force than existed in the magnets of the first machine. Thus, by having one machine to charge the electro-magnets of another, a very great electric current could be readily produced. This plan was adopted in the machine shown in the accompanying cut. (See Fig. 29.) A number of permanent magnets placed above produce in the armature rotating between them a current which charges the large electro-magnets below, and the armature rotating within these electro-magnets yields a current of great power.

107. Ladd of London has carried this idea yet farther

FIG. 29.

by dispensing with the upper machine, and causing part of the current developed by the large armature to circulate in the magnets around it. Some trace of magnetism will be found in any piece of iron, and this is enough to start the action, which, reacting on itself, soon brings the machine to its maximum energy of action.

108. These developments of electric action are not obtained without corresponding expenditure of force. The armatures are powerfully attracted by the magnets, and must be forcibly pulled away. Indeed, one of Wilde's machines when producing a very intense electric light requires about five horse-power to drive it.*

109. Not only do magnets develop currents of electricity in coils of wire, but also in any moving conductors, and the currents so produced react upon the magnets, and also in passing through the conductors themselves develop heat. Thus, if a copper disk or tube is rotated in a powerful magnetic field, it will become very hot; indeed, fusible metal placed in such a tube may even be melted. So, again, a disk of copper rotated under a magnetic needle will cause this to be displaced. The magnet induces currents in the rotating disk, and these in turn affect the magnet.

ELECTRICAL MEASUREMENTS. — *General Considerations and Definitions.* — 110. We have already at the outset, when considering the source of galvanic electricity, pretty fully discussed the meaning of electro-motive force, and have shown that it means simply the power of separating

* These machines are now employed with entire success to deposit copper for electrotyping, as at the establishment of Mr. L. L. Smith, 135 West Twenty-fifth street, New York, and for some lighthouses. An account of the magneto-electric machine of M. Gramme, in the London "Standard" of April 9, 1873, confirmed by other information, leads to the belief that a decided improvement has been made in these machines.

the electric fluids resulting from a difference in chemical attractions under certain conditions. We have compared this power, with reference to each of the fluids considered separately, to an imaginary property which we might suppose some substance to possess of forcing water through it in one direction until a slight difference in level had been established on opposite sides, when the action would be restrained by the hydrostatic pressure or head of the higher level. Now, it is evident that the quantity of liquid made to pass by such an action would depend on two things—on the intensity of the moving force (electro-motive force), and on the total resistance experienced to such motion, including both the resistance in the source of force itself (the sieve, for instance, in our illustration) and the channel by which the liquid could descend again to its first level.

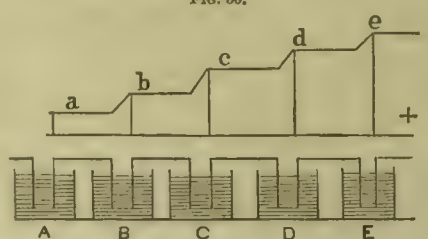
Clearly, if the propelling force were constant the amount of liquid moved (there being in this case no question of inertia) would be so much the more as the resistance was less, and *vice versâ*. We therefore see that this simple equation will express the relation between these three things; Q being the quantity of fluid moved, E the electro-motive force, and R the resistance: $Q = \frac{E}{R}$. This is the famous law of Ohm, on which is founded the whole science of electrical measurement.

111. We will now consider a few cases in detail as a means of more clearly understanding the relations of this principle. Suppose that we have a number of electro-motive elements, such as galvanic battery couples, and arrange them in series (*i. e.* each one working into the next, as it were), and have an outside connection so short and of such a good conductor that it will offer no appreciable resistance. What will be the quantity of fluid set in motion in such a case, as compared with what a single element would yield with the same good outside connection? To make our equation full in its expression, we would have $Q = \frac{E}{R + r}$ for the single element, and $Q' = \frac{nE}{nR + r}$ for the number of elements; R being the resistance of the element itself, and r that of the exterior connection. Now, it is evident that if $r = 0$, as we have supposed in the case taken above, the second equation becomes $Q' = \frac{nE}{nR} = \frac{E}{R'}$, or identical with the first; or, in other words, that the series of cells, however great their number, will set in motion no more fluid than a single one.

Let us give the above a numerical shape. Let $E = 50$, $R = 20$ and $n = 10$; then $Q = \frac{50}{20 + 0} = 2.5$, and $Q' = \frac{10 \times 50}{10 \times 20 + 0} = \frac{500}{200} = 2.5$.

112. Let us now consider the reason of this in the light of our illustration. Suppose we have a single sieve forcing water through a trough, and that this water can flow back with perfect freedom. There will then be no appreciable head acting against the sieve, and it will therefore force all the water that it is capable of transmitting. Now, suppose another sieve to take the water which has passed through the first; it will simply transmit it as did the other, without giving it any head or otherwise affecting it; for it must be borne in mind that we are not dealing with a dense material, which can acquire momentum, but with an imponderable fluid.

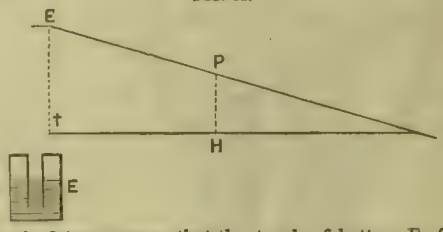
But now let us suppose that the exterior resistance was considerable—that, for example, the water raised to one side in the trough could only flow out by a narrow tube. Then clearly the sieve would produce a difference of level approaching that which was its maximum, and could then only pass on more water as the pipe allowed the accumulated quantity to flow back.* If, now, a second sieve were added to the first, it would take the water at the height to which the first sieve had raised it, and would raise it just as much higher, so giving it twice the head to force it through the pipe; and for a fluid without weight this would cause a double flow. Returning to our equation, we would then have this case expressed as follows, making r no longer equal to 0, but, say, to 30: $Q = \frac{E}{R + r}$ and $Q'' = \frac{nE}{nR + r}$; $Q = \frac{50}{20 + 30} = 1$ and $Q'' = \frac{10 \times 50}{10 \times 20 + 30} = \frac{500}{230} = 2.17$. In other words, in place of having the same quantity in both cases, as before, we now have more than twice as much in the one instance as in the other. It thus becomes evident that to obtain the best effect a certain proportion ought to exist between the exterior resistance and that of the electro-motor or battery, and our illustration will give us an easy way of seeing what this must be.



* Moreover, this flow would evidently depend for its quantity on the amount of head propelling it.

113. It is, in the first place, evident that if the resistance of the exterior circuit is greater than that of the battery, the latter will "pump up" the fluid faster than it can come down again, and that so its whole capacity will not be utilized; while, on the other hand, if the exterior resistance is less than that of the battery, then the latter will be doing unnecessary work in raising the fluid to a higher level and giving it a greater "head" to flow down than is needed to keep up the supply; or, in other words, that we could very greatly decrease the number of active elements, and thus the expenditure of force, and yet but little diminish the amount of fluid put in motion. Thus, suppose we have 30 elements, each with an electro-motive force of 12 and a resistance of 2, and have an exterior resistance of 40; then $Q = \frac{nE}{nR + r} = \frac{30 \times 12}{30 \times 2 + 40} = \frac{360}{100} = 3.6$. If we now take away 10 elements, or diminish the expenditure of material by one-third, we will have $Q' = \frac{nE}{nR + r} = \frac{20 \times 12}{20 \times 2 + 40} = \frac{240}{80} = 3$, or a diminution in the current of only .6, or one-sixth of its former amount.

These examples, with the foregoing definitions, render the meaning of electro-motive force and Ohm's law sufficiently clear; and we will therefore pass to the next point, or the meaning of the terms—



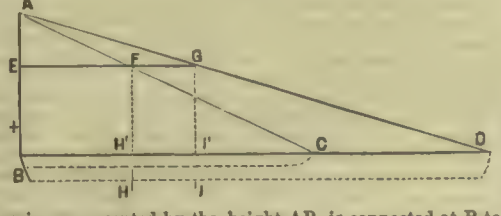
Tension or Potential.—114. These terms are used to indicate the condensation or accumulation of the fluids at any points, as compared with some standard assumed constant for the time being; or, turning to our former and convenient illustration, the tension or potential of any part of a circuit is the "head" or "hydrostatic column" of fluid at that point. Thus, suppose that A, B, C, D, E represented a series of galvanic elements or cells, with their negative pole connected with the ground at N, and the positive pole

FIG. 30.

insulated; then the successive levels a, b, c, d, e would indicate the + tensions of the various points, the relative tensions being expressed by vertical lines drawn to a common level. This shows us also at a glance the relation between electro-motive force and tension. The tension due to each cell equals its electro-motive force, and the total tension or maximum tension of the series is equal to the sum of the electro-motive forces; but the tension of each point is different, while the electro-motive force is uniform.

FIG. 31.

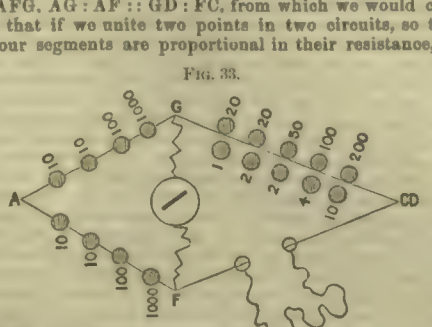
Again, let us suppose that the + pole of battery E of the last diagram were connected by a long wire with the earth at F; then the positive tension at F would be nothing, and at various points in the line would be represented by the heights of corresponding points on the line eF. Or, to revert to our hydrostatic comparison, suppose water to be supplied to a pipe GF at G, and to run out freely at F, the head at any intermediate point, H, might be supposed to be HI. As we have before remarked, we do not propose this as an illustration in hydraulics, though by adding the necessary conditions it could be carried out in that shape, but simply as giving a physical shape to the idea of the electric state, which may render it more easy to handle.



Derived Circuits.—115. When more than one passage is presented to an electric fluid, it will divide itself between them in proportion to the ease of passage, or inversely to the resistance. Thus, suppose two circuits open to the current, one offering a resistance of 9 and the other of 1 unit. Then one-tenth of the current will flow through the first, and nine-tenths through the second; and whatever be the

number, and however great the difference of the circuits, this rule will be rigorously carried out. Again, if two separate circuits have resistances of 2 in one case and 9 in another, and we wish to find what their resistance would amount to when they both acted together as parallel roads for the fluid, we easily derive it in this manner. If their resistances are 9 and 2 respectively, their conducting powers will be one-ninth and one-half, or the reciprocals of their resistances. Now, the sum of these, which would evidently be their united conducting power, would be $\frac{1}{9}+\frac{1}{2}$ $=\frac{2+9}{9\times 2}$; but this being the conducting power, the resistance is its reciprocal, or $\frac{9\times 2}{2+9}=\frac{18}{11}=1\frac{7}{11}$. But from the above example we can derive the rule—namely, the resistance of a compound of two parallel circuits is the product of the resistances divided by their sum.

116. One of the applications of this principle is in the use of what are called shunts. These are resistances bearing some convenient relation to that of the galvanometer used, and therefore diverting a proportional amount of the current, so that we can measure with an instrument a current which would otherwise be much too powerful. Suppose, for example, that we have a coiled wire whose resistance is to that of the galvanometer as 1 to 9; then the total amount of current transmitted will be that due to their "combined" resistance when they form parallel connections. Thus, $\frac{9\times 1}{9+1}=\frac{9}{10}$ will be the resistance of this "combined circuit," and hence its transmitting power will be $\frac{10}{9}$; while the galvanometer resistance being 9, its transmitting power will be $\frac{1}{9}$, or one-tenth of this; hence, with this shunt in action, the force measured by the galvanometer will be one-tenth of the total amount passing, and hence all its indications should be multiplied by ten. In the same way we may use shunts whose resistances are to those of the galvanometers as 1:99 or 1:999, and so measure the one one-hundredths and one one-thousandths of the current.



Measurement of Resistances.—"*Wheatstone's Bridge.*"—117. Suppose that the positive pole of a battery, with a

Fig. 32.

tension represented by the height AB, is connected at B to two wires, BC and BD, whose resistances are represented by the lengths of those lines, and that these lines are both connected with the earth at their ends, C and D respectively. They will then of necessity have the same tension at B, and none at all at C and D, and at any point between their tensions would be represented by the heights of lines drawn to AC and AD respectively. Now, if any line be drawn parallel to BD, cutting AC and AD, as at F and G, it is evident—1st, that the tensions of the corresponding points H and I of the wires will be equal, being measured by the equal lines FH′ and GI′, and hence that if these points were connected by a conductor no current would pass, as there would be no reason for it to go from F to G or from G to F. 2d, By the similarity of triangles ACD and AFG, AG : AF :: GD : FC, from which we would conclude that if we unite two points in two circuits, so that the four segments are proportional in their resistance, no

Fig. 33.

current will pass. We have only considered the one fluid, the positive, but of course the same reasoning would apply to the negative, and being true for each would be true for both.

Let us now consider an application of this general principle. Suppose that we have adjustable and known resistances so arranged that a battery current entering at A divides on AG and AF; that from G to CD are arranged other known resistances, while between F and CD we introduce some unknown resistance which we wish to measure. The points G and F are connected through a galvanometer.

118. Suppose, then, that we make the adjustable resistance on AG 10, and that on AF 100, and then introduce resistances on G–CD until the galvanometer ceases to show any current. We will then know that AG : AF :: G–CD : F–CD, or x. If therefore we had found it necessary to introduce resistances of 173 at G–CD, we would have 10 : 100 :: 173 : x, $x=1730$. This method, which admits of a very wide range of application, is perhaps more extensively used than any other.

With a double-coil galvanometer we may measure resistances by making the current divide and pass in opposite senses through the two coils. If each branch has an equal resistance, the two currents will be exactly equal, and their effects upon the needle or needles will neutralize each other. The unknown resistance being introduced in the one branch, we place known resistances in the other until a balance is obtained, and then know that the resistance so introduced equals the unknown one. Where the resistance is too great for our standards, we can, by introducing shunts on that side, increase their value 10, 100, or 1000 times. For resistances higher than can be measured in this way we note the deflection produced by the current, and compare it with that obtained with known resistances, either with or without shunts.

Induction.—119. This action in the case of insulated wires is exactly the same as that already discussed in the Leyden jar. It is measured by noting the deflection produced by charging and discharging the insulated wire immersed all but its ends in water connected with the other pole, and comparing this deflection with that obtained by like treatment with condensers of known capacity. The unit here used is the *farad*, for whose relations to other measures see "Electrical Units."

Resistance of Batteries.—120. With a double-coil galvanometer this measurement presents little difficulty. We connect one or more cells of the battery with a set of adjustable resistances, and pass the current through one coil of the galvanometer, introducing as much resistance as is necessary to bring the deflection to a sensitive point. We note this effect, and then know that it or $Q=\frac{E}{R+r+r'}$; R being the battery resistance, r the resistance of the galvanometer, and r' the additional resistance which we have introduced. We now pass the current through both coils in the same direction, and add resistance until we get the same deflection as before. We then know that since by passing twice as often round the needle the electro-motive force has been doubled in efficiency, and yet has only produced an equal effect, the resistances must all have been doubled. Now, r is doubled by the use of the second coil, and we know the amount of r', which is what we added to regulate the deflection; therefore any additional quantity which we have employed must be the duplicate of R, the battery resistance.

121. To compare the electro-motive force of batteries, we first determine their resistance, and then, connecting them successively to the same galvanometer, add resistances till they all make the same deflection; then their electro-motive forces will be inversely as the total resistances in the several cases, including those of the batteries themselves.

122. We have here given all the fundamental processes of measurement, but there are of course countless modifications which cannot be even named within our present brief limits. For these we must refer the reader to the works of Sabine, Clark, and Culley on this special subject, and to the numerous papers in the "Reports of the British Association" and in the scientific journals.

123. As a matter of interest to the general reader, we may mention that the location of faults in submerged cables is accomplished by the application in some modified form of one or other of the methods already described, according to the nature of the fault. Thus, if the fault is an entire rupture, it is located by comparing the resistance of the piece left with that of known lengths of the same wire. If the conductor is fractured inside of its insulating sheath, the inductive charge is measured, and we thus know how much wire remains on the nearer side of the break. Of course complicated cases require special treatment.

Electrical Units.—*The unit of resistance* or *ohm* has been already given at § 75.

The unit of tension or electro-motive force, or *volt*, does not differ much from that of a Daniell's cell. One million volts make a megavolt, and one-millionth of a volt is a

microvolt. Sir W. Thomson makes the volt equal to .9268; the electro-motive force of a Daniell's cell or the Daniell = 1.079 volts.

The unit of quantity is a farad, the megafarad and microfarad bearing the same proportion of a million times and a millionth as with the ohms and volts. The farad is that quantity of electricity which with an electro-motive force of one volt would flow through the resistance of one ohm in one second. *The British Association unit of current* is a current of one farad per second.

The Electro-chemical Unit.—Experiment shows that a unit current decomposes in one second 0.00142 grain of water, or liberates 0.0105 cubic inch of mixed gas.

HENRY MORTON.

Electricity, Animal. See ELECTRICITY, § 77, p. 1513, by PRES. HENRY MORTON, PH. D.

Electric Light is the result of heat produced by the force of electricity, which is usually evoked by the chemical reaction of a metal and an acid. This combination is termed a battery, and from its opposite ends the opposite kinds of electricity are conducted by wires, terminating in pencils of hard coke. These pencils being brought into contact and then separated, the opposing electric currents rush together to form again neutral electricity, and this act gives rise to a very great amount of heat. This heat will ignite the intermediate stratum of air to a point at which it evolves light, but this amount of light is small compared with that given out by the ignited ends of the coke pencils and the particles of carbon thrown off by these pencils. The most beautiful of all artificial lights is produced in this way.

In using the electric light it is found that the carbon points waste rapidly, the positive point especially so. One of the best methods of keeping the light constant is a device by Duboscq, whereby clockwork is made to move the points slowly towards each other—the positive at about twice the rate of the negative point. In order to prevent the points from striking each other the current is made to pass through a coil around an electro-magnet, which attracts a keeper, thus stopping the clock; but when the points are burned away the clock is started by the falling of the keeper, and the current is so quickly renewed (if the apparatus be good) that no sensible disturbance of the light takes place. This light is much employed for experimental purposes, and has been used with success in lighthouses.

Electric Telegraph. See TELEGRAPH, by FRANK L. POPE.

Elec'trodes (plu.), [from *electricity* and the Gr. ὁδός, a "way"], the surfaces by which electricity passes into and out of different media. The poles of the voltaic battery or pile are especially termed *electrodes*. The so-called positive electrode is the "anode," and the negative is the "cathode."

Electro-dynamic Engine, a form of engine in which electro-magnetism is the motive-power. Immediately after the invention of the electro-magnet in 1827 by Prof. Henry, the instantaneousness with which, in this contrivance, force may be developed, destroyed, or reversed, led many persons of an inventive turn to attempt its application to some useful purpose in the arts. Many forms of vibrating and rotating apparatus were constructed by Prof. Henry and others to illustrate the principle; but the first electro-dynamic engine, properly so called, was the invention of Thomas Davenport of Vermont, by whom it was exhibited to Prof. Henry in 1835, and brought out publicly in New York a year or two later. In this machine a number of fixed electro-magnets were arranged, with poles presented inward, upon the circumference of a horizontal circle, within which an equal number, V-shaped in form, with their branches in the direction of radii, revolved. By a system of pole-changing thimbles the battery current in the revolving magnets was reversed at the moment of nearest approach of the fixed and movable poles, so that during approach they were attracted towards each other, and after the passage repelled. The success of a small machine of this construction was such as to encourage Mr. Davenport to attempt one on a scale sufficiently large, by calculation, to drive a power-printing-press; but this last proved a complete failure, and the engine was heard of no more. The discrepancy in this case, as in many others where similar disappointment has been encountered, between calculation and experimental results, was in great part owing to the fact that moving magnets, whether permanent or temporary, always generate, in closed conducting circuits in their neighborhood, secondary or induced electric currents, which act in opposition to the primary currents, and tend in all electro-dynamic engines to diminish the effective energy of the magnets, whether they act by attraction or by repulsion. But had not this difficulty existed, the engine would hardly have been an economical success, since the materials consumed in the battery, metallic zinc and acids or salts, are products of industry prepared by the aid of heat; and the heat necessary for such preparation is capable, if directly applied to the production of steam, of performing a larger amount of work than would be derived from the electro-dynamic engine, even were it not subject to the disadvantage above mentioned. Indeed, it has long since been regarded as settled that motive-power derived from electro-magnetic combinations can only be secured at an expense which forbids its employment upon a large scale; but for many minor purposes, in which the consideration of cost is unimportant, the convenience of application of this power has secured for it an acceptance which in France and England is becoming every year more general.

The extensive introduction into families of the sewing-machine has created a special demand for small powers; and it is here that the electro-magnetic engine finds a field of usefulness to which it is peculiarly adapted. An engine of this kind, the invention of Mr. J. H. Cazal of Paris, was exhibited in the Universal Exposition of 1867, and received from the jury the distinction of an honorable mention. This is exceedingly compact, and as the driving machinery takes the place and has the appearance of the fly-wheel of the common sewing-machine, it adds nothing to the weight or to the seeming complication. It is formed of a thick disk of soft iron cut into the shape of a gear-wheel, a deep groove being afterwards cut down in the middle of the circumference, which is wound with insulated wire. The ends of the wire are soldered to insulated thimbles, which, by means of tangent-springs, introduce the battery current in the usual way. Surrounding this magnetic wheel is a heavy iron ring, indented on its interior surface in a manner to present elevations corresponding to the teeth or salient points of the wheel. This ring is fixed, and the whole apparatus is more or less concealed by a neat annular metallic envelope. When the teeth of the wheel pass before the prominent parts of the surrounding ring, there is a near approach to contact, and the attraction is strong. When these teeth are halfway between those points, the opposite attractions are balanced. At the moment of nearest approach the current is arrested; it is renewed again at the intermediate position. In the interval, while the current is not flowing, the magnetic wheel maintains the motion in the manner of a fly-wheel.

Another engine was exhibited in the same exposition by a company calling itself the Birmingham Electro-Magnetic Manufacturing Company, established at Birmingham in England. This engine is provided with four sets of fixed electro-magnets of the U or horseshoe form, two sets at each end of an oscillating beam, by which the power is to be utilized. The magnets of each set are arranged in two tiers, one above the other. The armatures of these several magnets are carried by rods depending from the ends of the beam, but the rods pass freely through these armatures, without being fastened to them. When, therefore, an armature, in the descent of the rod, comes into contact with the magnet to which it belongs, the rod continues its motion, and leaves the armature resting there. In the return motion the rod lifts the armature again by means of a collar or enlargement which has been given to it at the place intended. Each armature has thus its collar, and these several collars have been so fixed upon the suspended rods that the armatures reach the faces of their respective magnets successively, and no two at the same time. In the action of the machine the battery current actuates the magnets on the side of the descent, while on the other side the current is cut off. The machine acts therefore only by attraction. The armatures are of soft iron. As these armatures approach their magnets successively, it will happen that whenever one becomes inefficient, by coming into contact with its magnet, the next will be in position to exert a very high attractive force. And this force increases until this next makes contact with its magnet in like manner. The arrangements of this machine, though extremely simple, are not unfavorable to the object of securing the largest amount of effective power from a given battery current.

A third motor of this class, which made its appearance at the same Exposition, was the invention of Kravogl of Innsbruck in the Tyrol, and is described by Robert Sabine, Esq., member of the British commission to the Exposition, to be "a hollow heavy wrought-iron wheel, rotated by means of a permanent magnet creeping up inside it. In principle, the apparatus resembles exactly a treadmill. Inside the outer case of iron, in the centre of the section, is a circular tube of brass, and in the annular space between the two tubes three coils of insulated wire are wound at right angles to the tangents of the periphery, and connected with contacts properly placed at the axis. Inside the interior brass tube or ring is a magnet carried on anti-friction wheels, and occupying perhaps one-third of the whole circle. When a current is sent through the wire surrounding the magnet, the latter is deflected, or creeps up the ring on one side or

the other according to the direction of the current, and by doing so displaces the centre of gravity of the whole system towards that side. In consequence, the wheel must turn slightly on its axis to compensate this displacement. But while it does so the magnet creeps up still farther, so that the wheel acquires a continuous rotatory motion. There is very little friction in this machine, and it is probably one of those in which the equivalent of mechanical force, gained by an expenditure of a unit of current, would be found the highest. This is not saying much, however, for in the best constructed machine this found value must fall far short of the theoretical equivalent." From this statement it appears that, whatever may be the coefficient of effective force in the machine described, the absolute amount of work which it is capable of performing must always be extremely limited, since at maximum it cannot exceed the weight of the magnet lifted through a space equal to that described by a point in the periphery of the wheel, taken at the mean distance of the magnet from the centre of motion. In the machine exhibited the magnet, though of course concealed from observation, could not, from the visible dimensions of the apparatus, have exceeded a pound or two in weight. To construct a machine on this principle of any considerable power it would be necessary very greatly to enlarge these dimensions.

Many other inventions of this kind might be enumerated, but the foregoing will suffice to show the principles on which they must all depend. F. A. P. BARNARD.

Elec'tro-Dynam'ics is the science which treats of the phenomena of electric currents. (See ELECTRICITY, by PRES. HENRY MORTON, PH. D.)

Electrol'ysis [from *electricity* and the Gr. λύω, to "set free"], the chemical decomposition of a substance by means of electricity. If the poles of a galvanic battery are terminated by slips of platinum, and these are immersed in water slightly acidulated with sulphuric acid, they will immediately become covered with bubbles of gas, which soon begin to rise through the water, and these gases will be found to be oxygen and hydrogen, the two components of water; the oxygen rising from the positive and the hydrogen from the negative pole. This process can only take place when the substance to be decomposed is in the liquid state; for it includes, if it does not wholly depend on, a convective action, during which the parts of the body are transferred, one to one side, the other to the other; and it therefore requires the free mobility of the liquid form. During electrolysis the components of the electrolyte are resolved into two groups, one of which goes to the positive pole, and the other to the negative pole; and the electrolytic action of the current is the same at all parts of the circuit. The quantity of the electrolyte decomposed in a given time is in simple proportion to the strength of the current; and the same quantity of electricity decomposes chemically equivalent quantities of different electrolytes. When several electrolytes are mixed, a strong current will generally act a little on all of them, and the quantity in which the elementary bodies appear will depend upon the quantities of the compounds in the mixture, and on the relative ease with which they yield to decomposition.

Electro-Magnetism. See ELECTRICITY, by PRES. HENRY MORTON, PH. D.

Electro-Metallurgy. See ELECTROTYPE.

Electrom'eter [from *electricity* and the Gr. μέτρον, a "measure"] is sometimes used as the name of an instrument employed in detecting electric excitation, but more commonly called electroscope; but the term properly designates those instruments by which the attempt is made to measure the amount of the electric force. Coulomb's electrometer measures this force by the amount of twist it will give to a silken thread; others measure the arc through which a suspended pith ball is repelled by electricity.

Electroph'orus [from *electricity* and the Gr. φέρω, to "produce"] is an instrument for obtaining electricity by means of induction. A shallow brass or tin tray, called the form, is filled with a compound of equal parts of shell-lac, resin, and Venetian turpentine. A tin plate with well-rounded edges and a glass handle is made to cover the resinous plate very nearly, without approaching too closely to the edges of the form. The resinous plate is then struck or rubbed with warm and dry catskin or flannel, and thus becomes negatively electrified. The tin plate is placed on the resin and touched by the finger, which conducts off a certain amount of the natural negative electricity of the tin plate; the latter has therefore become positively electrified, and on withdrawing the finger and raising it will furnish a positive spark. As the negative electricity of the resin acts only inductively, the process may be repeated indefinitely.

Electro-plating is the covering of the surface of articles formed of the cheaper metals with gold, silver, platinum, nickel, copper, or other costly metal by means of the electric current, on the same principle as that which is employed in electrotyping. German silver is one of the best substances to receive an electro-plate, though copper and its alloys are excellent. If iron, zinc, or pewter are to be used, they are first plated with copper, and they then readily take the electro-plate of gold or silver. All articles to be plated are most carefully cleaned and scoured. They are then dipped in a solution of nitrate of mercury, and receive therefrom a thin film of mercury, which causes the plate to adhere firmly. The bath of silver, gold, or platinum contains 100 parts of water, 10 of potassium cyanide, and 1 of the cyanide of the precious metal to be employed. The articles to be plated are suspended in this bath, and treated as described in the article ELECTROTYPE (which see). After removal, they are brushed and burnished. The above account is necessarily very general, for though the principle is simple, there are in practice many details which require careful attention in order to secure success. This process is of great importance in the arts, one of its latest applications being the operation of NICKEL-PLATING (which see.)

Elec'troscope [from *electricity* and the Gr. σκοπέω, to "see"], an instrument for the detection of the presence of electricity. Suspended balls of pith or slips of gold-leaf, from their extreme lightness, will readily diverge from each other; and this, or some similar device, is the essential element of most electroscopes. They depend for their action on the elementary law, that bodies charged with like electricity repel, while those charged with unlike electricity attract each other. The electroscope most used is Bennet's gold-leaf electroscope. This consists of a glass shade with a wide mouth, which is closed by a wooden stopper which can be taken out and replaced at pleasure. A glass tube passes vertically through the centre of the wooden stopper, while a metallic rod is fixed in the centre of the glass tube. The lower end of the rod terminates in a small flat plate, to the sides of which two narrow strips of gold-leaf are soldered, and are thus attached opposite each other; and the upper end of the rod is furnished either with a circular horizontal plate or with a brass knob. If an electrified body be brought near to the top of the instrument, the top becomes electrified oppositely to the body presented, and the gold leaves similarly. As they are both charged with the same kind of electricity, they repel each other, and diverge more or less in proportion to the strength of the charge and to the nearness of the electrified body; and thus show us the presence of free electricity. Besides Bennet's electroscope, there are the single gold-leaf electroscope, Volta's condensing electroscope, and Bohnenberger's electroscope.

Elec'trotint, an art by which drawings are made with any substance insoluble in the solution of sulphate of copper. When the design is completed the plate is immersed in the solution, and a reverse made by the electro-coppering process, called electrotype or voltatype.

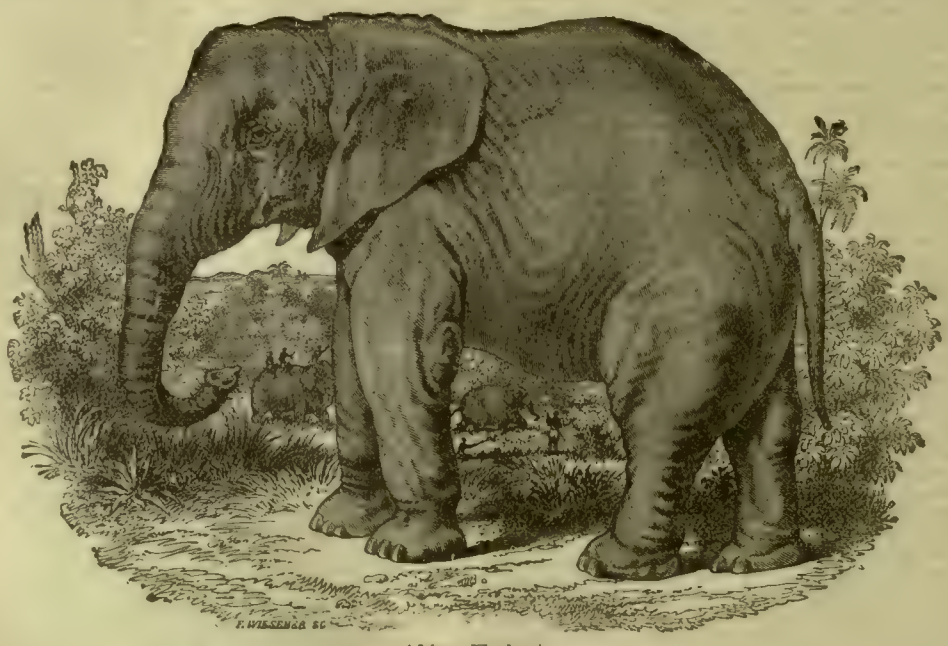
Elec'trotype [from *electricity* and *type*] is the name given to the cast of an object procured by the gradual deposition of a metal from a solution by means of a current of electricity. When two pieces of clean platinum are put into a solution of sulphate of copper, no change takes place. But if an electric current is transmitted through the solution by means of these platinum plates, copper is at once precipitated upon the platinum, which forms the cathode, the anode remaining clean. If the current be reversed, the copper will be transferred from the platinum plate on which it had been deposited to the clean plate. By thus reversing the direction of the current the copper may be sent backward and forward, being always deposited upon the negative pole, or that surface by which the electric current leaves the electrolyte or solution that is undergoing decomposition. By continuing the electric currents, and keeping up the strength of the solution by adding fresh portions of the salt of copper, the metallic film on the cathode may be made of any required thickness, and afterwards peeled off the platinum surface. The texture of the copper deposited varies with the battery-power employed and with the strength and temperature of the solution, and may be hard, brittle, and crystalline, or tough and malleable, according to the management of the operator. A current of low intensity, a moderately strong solution of sulphate of copper acidulated with sulphuric acid, and a temperature not below 60°, are the most favorable circumstances for obtaining the best deposit of copper. When the negative pole or cathode is irregular (like a coin or medal), instead of being a plane surface of platinum, an exact impression of the device may be taken off on the precipitated copper. Gold and other metals may be substituted for copper by proper management, or if the pre-

cipitated metal be left upon the surface on which it is thrown down, gilding, silvering, etc. may be done extensively and with fine effect. This art is called electro-plating. Proficiency in electrotyping or the galvano-plastic art requires but little apparatus, and involves no great expense. A medal may be either copied directly, and an inverted impression obtained from which a second electrotype can be taken, or a cast of the medal may be first made in stearin or plaster. In the latter operation, which is the most generally used, the mould, if of plaster, must be first soaked in oil, tallow, or melted spermaceti, so as to render it impervious to water. It must then be made a conductor of the current, and this is done by thoroughly brushing black lead over the surface which is to be reproduced. In case the medal itself is used, in order to prevent the deposition of copper which would take place upon the edges and upon the reverse of the medal, those parts should be covered with sealing-wax, varnish, or shell-lac. The introduction of this valuable art has been ascribed to different persons. Daniell is said to have been the first to notice the deposition of metallic copper by electricity while working with his battery; Jacobi of St. Petersburg first published in 1839 a practical application of this fact, which publication called out announcements from Spencer and Jordan, two Englishmen, who were both working independently at the same object as Jacobi. Messrs. Elkington soon after applied the process to the gilding and plating of goods on a large scale. Electrotyping has to some extent superseded the old stereotype process for making plates for printers' use, especially for the reproduction of engravings and where large numbers are to be printed. (See ELECTRICITY for the explanation of the electrolytic action and apparatus employed. For a summary of the various processes used by printers in the departments of stereotyping and electrotyping, see PRINTING.)

Elec'trum, the Latin name of AMBER (which see); also a natural alloy of gold and silver, in the proportion of two of gold and one of silver. It is found in Siberia, Norway, and California, and occurs in tabular crystals or imperfect cubes of a silver-white color.

Elec'tuary [Lat. *electua'rium,* from the Gr. ἐκ, "out," and λείχω, to "lick," because designed to be licked with the tongue from the spoon], in pharmacy, a variety of confection thinner than a conserve, and composed of powdered drugs mingled with honey, syrup, glycerin, or other vehicle. Electuaries are not now recognized in the U. S. and British pharmacopœias.

El'egy [Lat. *elegia;* Gr. ἐλεγεία; Fr. *élégie;* Ger. *Elegie*], the name given by the ancient Greeks and Romans to poems of various kinds, being applied to the martial lyrics of Tyrtæus, the aphorisms of Theognis and Solon, the melancholy effusions of Mimnermus, and the erotic poems of Ovid, Catullus, and Tibullus. In modern times the name is applied chiefly to poetical compositions of a melancholy character.



El'ement [Lat. *elemen'tum;* Fr. *élément*], a term used in various senses; a first principle; a rudiment; a constituent part of a compound; sometimes the proper state or sphere of a person or an animal. In the plural, the first principles or rules of a science or art; also the bread and wine in the Eucharist. Ancient philosophers applied this term to fire, air, earth, and water, each of which, in their several systems, was supposed to be the first principle of all things. The elements of the alchemists were sulphur, mercury, and salt. As a modern scientific term, *element* signifies a simple substance, or one which chemists have not yet decomposed.

ELEMENTS, in astronomy, are the data required in order to compute the place of a planet, satellite, or comet; those numerical quantities, etc. which are employed in the construction of tables exhibiting the motions of the moon and planets. They comprise the greatest, least, and mean distances of the planets from the sun, the eccentricity of their orbits, their mean motions, daily and annual, their masses, densities, etc.

Elements, Chemical. See CHEMISTRY, by PROF. GEORGE F. BARKER, M. D.

El'emi, the name of a fragrant resinous substance procured from several species of trees of the natural order Amyridaceæ. It exudes from incisions made in the bark, is at first soft, but becomes hard and brittle. It is generally pale yellow, semi-transparent, and soluble in alcohol except a residue called *elemin.* It is obtained from the *Icica Icicariba,* which grows in Brazil; from *Elaphrium elemiferum,* of Mexico; and from *Canarium commune,* of Manila. Elemi is used in the preparation of ointments and plasters.

El'ephant [Gr. ἐλέφας; Lat. *elephas,* gen. *elephantis*],

African Elephant.

a gigantic animal of the order Proboscidea, is the largest and heaviest of existing quadrupeds, and is celebrated for sagacity and docility. The genus is characterized by having grinders composed of alternating vertical plates of ivory, enamel, and cæmentum; and two ivory tusks in the upper jaw. Elephants are the only living Mammalia that have a proboscis or trunk longer than the head. Cuvier included the genus *Elephas* and the extinct mastodon in a family of pachyderms, which he called Proboscidians. The proboscis is a very remarkable feature, and presents an astonishing combination of flexibility and strength. It is an organ of touch, is four or five feet long, has neither bone nor cartilage; and this constitutes the peculiarity of its mechanism. Two tubes or canals, which are prolongations of the nostrils, extend through its whole length. The mechanism of the trunk is unique among animal structures, and renders it capable of performing operations as different as picking up a pin and tearing up a tree by its roots. The animal uses his trunk to convey food and drink into his mouth, but he rarely uses it as a weapon. As an organ of touch the trunk is exquisitely fine. The elephant has so high an opinion of the importance of its trunk that when

attacked by a tiger or exposed to other danger he carries it high in the air. The tusks, which correspond to the canine teeth of other quadrupeds, sometimes measure nine feet in length and weigh 150 pounds each, but the average weight is not over 100 pounds. The tusks are formidable defensive and offensive weapons. The curvature of the tusks is subject to great variations. Some of the Indian elephants have their tusks varying from a projecting horizontal but rather elevated curve to a form almost straight. Others resemble in shape the letter S. Although the substance of which they are composed, called ivory, is different from the bone of other teeth, it is formed, like other teeth, by successive secretions from a pulpy root. The tusk has no adhesion to this root, but is held in its alveole (socket) as a nail is held in a plank. The elephant feeds on vegetable food exclusively, and the construction of its grinding teeth is a striking example of the adaptation of the teeth of every animal to its peculiar mode of subsistence. The duration of the teeth of quadrupeds is in proportion to their ordinary term of existence. To an animal that feeds on grass, leaves, etc. the destruction of the teeth involves a speedy death. Each grinder is composed of vertical laminæ covered with enamel, and joined together by a substance like ivory. This latter, being much softer than the enamel, wears away faster, so that the enamel remains higher, and the surface of each grinder always presents several ridges. Thus, by the renewal of the grinding surface the teeth of the elephant will last 100 years or more. According to Pliny and Aristotle, the elephant is capable of living 200 years.

Besides many species which are extinct, the genus *Elephas* comprises only two species now living—namely, the Asiatic or Indian elephant (*El'ephas Indi'cus*) and the African (*El'ephas Africa'nus*). The former has small ears and a concave forehead, and its skull is higher in proportion to its other dimensions. The forehead of the African species is somewhat convex, and it has enormous ears, which cover the shoulders. The ear is the most conspicuous external character by which the two species may be distinguished. The height of the Indian elephant from the ground to the top of the shoulder seldom exceeds ten feet. The African is larger, and sometimes measures twelve feet high. F. Cuvier and others regard it as of a distinct genus, and name it *Loxodonta Africana*. There is a skeleton of an elephant in the Museum of St. Petersburg which measures sixteen and a half feet in height.

A large elephant weighs about 7000 pounds. The ordinary period of gestation is twenty months and some days; only one calf is produced at a birth. The quantity of food consumed daily by a full-grown elephant is enormous, probably not less than 300 pounds. The skin is hard, thick, and nearly naked, or furnished with a few scattered hairs.

The Asiatic species is found in all the southern countries of Asia and in the adjacent islands. The African abounds in nearly all parts of the continent S. of the Desert of Sahara. Both species live in large herds, reigning the almost exclusive occupants of immense forests, and marshy plains covered with long grass and jungle. Their favorite habitat is in well-watered regions and plains or lowlands where the vegetation is luxuriant. It is stated that more than 1000 have been seen in one herd. "A herd of elephants," says Pringle, "browsing in majestic tranquillity amidst the wild magnificence of an African landscape, is a very noble sight." The people of Africa do not tame the elephant or use it as a beast of burden, but they kill great numbers for the sake of the ivory, which they sell, and the flesh, which they esteem as food. "There were periods in the history of the refined nations of antiquity when the destruction of the elephant was as great as in modern times; when Africa yielded her tribute of elephants' teeth to the kings of Persia: when the people of Judæa built ivory palaces (Psalm xiv. 8); when the Etruscan attributes of royalty were sceptres and thrones of ivory; when the ancient kings and magistrates of Rome sat in ivory seats (*sellæ curules*): and when colossal ivory statues of their gods were raised by the Greeks of the age of Pericles." (*Library of Entertaining Knowledge.*) The ancient Carthaginians and other nations employed elephants in war, not only as beasts of burden, but as combatants. These animals formed part of the army which Hannibal led across the Alps, and they are said to have decided the victory at the battle of Trebia. For a long period the elephant was as important an arm of war as the artillery of modern nations. The Asiatic species was also employed for this purpose, and Seleucus is said to have had more than 100 elephants at the battle of Ipsus.

The African hunters shoot them in the head or heart with rifles, and sometimes disable them by cutting the hamstring or tendon of the hind leg with a sword. Two hunters, naked, mounted on the back of the same horse, will approach an elephant, and when he assumes the offensive will retreat in a circuitous course with many devious turns. At length, one of the men, armed with a sword, alights on the ground near the elephant, and while the horseman occupies his attention in front the footman cuts the tendon just above the heel. At this critical moment the horseman wheels, takes his companion up behind him, and rescues him from the enraged animal by riding off at full speed. The chase of the elephant is attended with great danger, and many hunters have been killed in it. It appears that no people of Africa now capture elephants alive, or avail themselves of their services in a domesticated state, but in Asia large numbers of them are caught and tamed. The various modes of capturing wild elephants in India have prevailed without much change for centuries, and are practised in several Asiatic countries where elephants are required to maintain the splendor of Oriental luxury and figure in the pomp and pageantry of monarchs. In 1794 the nabob of Oude went upon a hunting expedition with 1000 elephants. The rudest mode of capturing them is by digging a pit which is covered with loose boards or with boughs and grass, and a tame elephant decoys a herd of them to tread on the trap. Pliny, who mentions the taking of elephants in pits, says the companions of one who has been thus entrapped will endeavor to liberate him by throwing materials into the pit. In other methods of capturing them man avails himself of the docility of tame female elephants, who serve as decoys and display a treacherous ingenuity as well as a desire to assist their masters in this business. While the female by her caresses diverts the attention of a wild animal, one hunter fetters his fore legs with a strong rope, and another ties his hind leg to a tree. If no tree is near in the first instance, they fasten to his leg a long cable, which trails behind him when he moves, until he comes near a large tree, to which he is secured. He is kept bound in that position until his rage is exhausted, and he is left to the further operation of hunger until he is subdued into docility. Among the animals which will attack an elephant are the tiger and rhinoceros. The animals to which the elephant is most nearly allied are the horse, pig, and rhinoceros.

According to Pliny, it was not uncommon at Rome to see tame elephants hurl javelins in the air and catch them with their trunks, and then execute a pyrrhic dance. They also danced upon a rope. This feat of dancing or walking on a rope is confirmed by other ancient writers. One of the strongest instincts of the elephant is that which impels him to try the stability and strength of any structure or surface which he is required to cross, before he will expose himself to the risk of breaking it down with his weight.

Remains of extinct species of elephant have been found in many parts of Europe, North America, and Siberia. Among them is the mammoth (*Elephas primigenius*), which occurs in the post-pliocene deposits. An entire specimen was discovered in 1799 in the frozen soil at the mouth of the river Lena in Siberia. (See MAMMOTH.) In the cave of Kirkdale, Yorkshire, England, the bones of elephants were found by Prof. Buckland, mixed with those of the rhinoceros and hyæna. Many of these fossils have also been dug up in the U. S., near the Ohio River and at other places. "There is not a canton in Siberia," says Pallas, "which does not possess fossil bones of elephants." Their tusks are there so abundant as to be an important article of commerce.

WILLIAM JACOBS.

Elephan'ta, an island of British India, in the harbor of Bombay, 7 miles from that city, derived its name from a gigantic stone figure of an elephant which formerly stood on the shore. The island is 6 miles in circumference. Here are several remarkable ancient cave-temples excavated out of the native rock, and adorned with numerous sculptured figures of the Hindoo mythology. The largest of these cave-temples is about 133 feet long, and is supported by twenty-six pillars.

Elephant Bay, an inlet of the Atlantic, in Benguela, Africa, is in lat. 13° 14′ S., lon. 12° 33′ E. It affords good anchorage, but no fresh water.

Elephanti'asis [from the Gr. ἐλέφας, an "elephant," because it was fancied that the legs of those who suffered with it resembled those of an elephant], as at present used, designates the disease anciently known as *elephantiasis Arabum*, the "elephantiasis of the Arabians," so called to distinguish it from the *elephantiasis Græcorum*, the "elephantiasis of the Greeks," which was probably identical with leprosy. Elephantiasis is rare in Europe and North America, though not unknown in either. It is endemic in the Levant and the East and West Indies. The foot and leg, or sometimes other parts, become greatly enlarged and enormously increased in density and hardness, the skin assuming a remarkable roughness and usually a darkness of hue. The prognosis is usually grave, very few cases recovering, though many cases remain completely station-

ary after the disease is once established. In fatal cases suppuration and erysipelas are the active symptoms. The treatment is thus far unsatisfactory. The use of iron, iodine and quinia, with bandaging, is recommended.

Elephan'tiné, an island of the river Nile, on the boundary between Egypt and Nubia, is opposite to Asswân (the ancient *Syene*). It is 1 mile long, and is partly occupied by gardens and houses interspersed among ruins of ancient temples erected by the Pharaohs. Among its monuments is the Nilometer mentioned by Strabo, and designed to record the height of the inundations of the Nile. It was long an independent city with its own kings. This island was garrisoned by the ancient Persians and Romans. It is now inhabited by Nubians.

Elephant Seal (*Macrorhinus proboscideus*), sometimes called the **Proboscis Seal** and **Sea Elephant,** is by far the largest of the Phocidæ or seal family, being sometimes thirty feet in length, and having a circumference at the thickest part of nearly eighteen feet. The color is generally bluish-gray, but occasionally dark brown. Its body is unevenly covered with short hair, the tail not more than six inches long, the swimming paws very large and strong, and having five nails; the hind paws, which are constructed like the webbed foot of a bird, are without even the rudiments of nails. The head is large, the eyes large and prominent, and there are no external ears. The canine teeth resemble tusks in their size and massiveness; the nose of the male is prolonged into a proboscis about a foot long, which, however, does not serve the same purpose as that of the elephant. The skin is very thick and strong, and is of great value for harness-making; the flesh is dark and unwholesome, the tongue only being prized as food. These seals are found in the Falkland Islands, South Georgia, Kerguelen's Land, etc. They are hunted to a great extent for their oil, which is of excellent quality and yielded in great quantity, one seal sometimes affording seventy gallons. They migrate to the south early in the summer, and northward in the beginning of winter. They feed chiefly on cuttlefish and other cephalopods.

Elephant's Foot (*Testudinaria elephantipes*), a plant sometimes called "Hottentots' bread," belongs to the order Dioscoriaceæ, having a large, fleshy root-stock, abruptly truncated at the end. This root-stock is eaten by the Hottentots. It is covered with a soft, rough bark, from which springs a climbing stem, bearing the leaves and flowers. The same name is also given to a genus of the order Compositæ (*Elephantopus*), of which two species are found in the southern Atlantic States.

Eletz, a town of Russia, in the government of Orel, 220 miles S. S. E. of Moscow, on the Sosna. It has many factories, and has a large trade in wheat flour. Pop. in 1867, 30,182.

Eleusi'ne, a genus of grasses (Graminaceæ), comprises several species which are natives of India and other warm climates, and are cultivated for food. *Eleusine Coracana* is extensively cultivated for its large farinaceous grain in India, China, and Japan. The grain called *tocusso* in Abyssinia is produced by the *Eleusine Tocusso*. The *Eleusine Indica* is naturalized about dooryards, etc. in the U. S.

Eleusin'ia, or **Eleusin'ian Mys'teries** [Gr. Ἐλευσίνια], an annual festival celebrated in ancient Greece in honor of Demeter (Ceres) and Persephone (Proserpine). The worship of Demeter originally took place at Eleusis only, but after the conquest of that city by the Athenians feasts were celebrated in her honor in various Grecian cities. The origin of these mysteries is uncertain, but the popular tradition was that Demeter herself, while searching for her daughter Persephone, came to Attica, where she taught the inhabitants the use of corn and instituted the mysteries. The festival consisted of the greater and the lesser mysteries. The lesser feast was held in the month of Anthesterion at Agræ, on the Ilissus, and was only a preparation for the real or greater mysteries. The latter took place in the month of Boëdromion, beginning on the 15th and ending on the 23d. On the first day, called ἀγυρμός (the "assembling"), the mystæ—*i. e.* those who had been initiated in the lesser Eleusinia—assembled at Athens. On the second they walked to the sea in procession and were purified. The third day appears to have been a day of fasting, and, according to some authorities, sacrifices of fish and cakes of barley from the Rarian plain were offered. On the fourth day the procession of the sacred basket (κάλαθος κάθοδος) took place. This basket contained pomegranates and poppy-seeds, and was drawn on a cart by oxen, and followed by women bearing mystic cases. The fifth day appears to have been known as the torch-day, and probably symbolized the search of Demeter for Persephone. The mystæ walked with torches to the temple of Demeter at Eleusis, where they seem to have remained all night. The sixth day, called Iakchos, from a son of Demeter, was the most solemn of all. A decorated statue of Iakchos was carried from Athens to Eleusis, where the votaries again passed the night and were initiated into the last mysteries. Under an awful oath of secresy they were admitted into the inner sanctuary, where they were allowed to see the sacred things, after which they were called *epoptæ*—*i. e.* "contemplators." On the seventh day they returned to Athens with jests and music, resting at the bridge over the Cephisus, where they ridiculed all who passed. The eighth day is supposed to have been added to the original number, so that those might be initiated who had been unable to attend on the sixth day. On the ninth and last day two vessels filled with wine or water were emptied—one towards the east, the other towards the west—by the priests, who at the same time uttered some mystical words. Besides these ceremonies there were several others, of which the Eleusinian games, supposed to have taken place on the seventh day, and to have been the most ancient in Greece, were the chief. Nothing certain is known respecting the doctrines revealed to the initiated, but they are supposed to have contained comforting assurances with regard to a future state. Distinctions of class were abolished at the Eleusinia, and with this view Lycurgus forbade any woman to ride in the procession in a chariot, under penalty of a heavy fine.

Eleu'sis [Gr. Ἐλευσίς or Ἐλευσίν], an ancient and celebrated city of Greece, was situated in Attica, near the northern shore of the Gulf of Salamis, and about 12 miles N. W. of Athens. It was the chief seat of the worship of Ceres, whose mystic rites, called ELEUSINIAN MYSTERIES (which see), were here performed annually with great pomp. Here was a large temple of Ceres. The site of Eleusis was near the modern village of Levsina. (See WORDSWORTH, "Greece," 1853.)

Eleu'thera, one of the Bahama Islands, in the Atlantic Ocean, is about 50 miles N. E. of New Providence. It is 80 miles long and about 10 miles wide. The soil is rather fertile, and produces pineapples, oranges, cascarilla bark, etc. Lat. of the northern point, 25° 34′ N., lon. 76° 43′ W.

Eleuthe'ria [from the Gr. Ἐλεύθερος, "free"], a national festival of the ancient Greeks, instituted in 479 B. C. to commemorate their deliverance from the Persian armies which had invaded Greece. It was celebrated annually at Platæa in the early part of autumn.

Eleva'tion [Lat. *eleva'tio*, from *el'evo, eleva'tum*, to "lift up" or "raise"], the act of raising to a higher level or place; the act of exalting in rank; altitude; height above the surface; sometimes exaltation of mind or style; a hill or elevated ground. In engineering and architecture, a geometrical representation of a building or other object, as if *projected* (hence also styled a *projection*) upon a vertical plane by perpendicular lines drawn through its defining lines or points. It differs from a true *pictorial* representation or perspective view in this, that the projecting lines in the latter converge to the eye, as do visual rays; from a *section*, in that the latter represents, instead of the *visible exterior*, what would be exposed to the eye were all that part of the object *in front* of an intersecting vertical plane removed.

ELEVATION, in astronomy, the angular height or the altitude of a celestial object above the horizon, measured by the arc of a vertical circle passing through it and the zenith. Thus, the elevation of the pole denotes the arc of the meridian intercepted between the pole and the horizon, and is always equal to the latitude of the observer. The greatest elevation of a star occurs when that star is on the meridian.

ELEVATION in gunnery is the inclination of the axis of the cannon or gun above the object aimed at, to counteract the effect which the force of gravity causes. It varies with the range.

Eleva'tion, a township of Johnston co., N. C. Pop. 1459.

Elevation of the Host (*eleva'tio hos'tiæ*), in the Roman Catholic ritual of the mass, is the lifting up of the elements after consecration for the adoration of the people.

Elf, plu. **Elves** [Ang.-Sax. *ælf*; Ger. *El'fe*; Swed. *elf*; Dan. *alf*]. Elves are a class of imaginary beings whose existence is especially believed in among the peasantry of Scandinavia and North-western Europe, in whose mythology they had a prominent place. They were of two kinds, the good and bad elves, and their exploits gave origin to a great number of marvellous tales. It appears that the elves were celebrated among Germanic peoples, and especially among the Norse, while fairies were described in Celtic legends; but in England, at least, the names were confounded.

Elf Ar'row-heads, called also **Elf Stones,** etc., the popular name in Great Britain of the flint arrow-heads which were used by the pre-historic inhabitants. Accord-

ing to a prevailing superstition, they were shot at human beings and cattle by the fairies or elves. These stones are worn as a talisman against witchcraft and poison.

El'gin, a royal burgh of Scotland, the capital of the county of Moray or Elgin, is on the river Lossie, 5 miles from the sea and 118 miles N. of Edinburgh, with which it is connected by a railway. It is beautifully situated in a fertile valley, has ten churches, a hospital, and an institution which Gen. Anderson endowed with £70,000 for the education of orphans. Elgin has the ruins of a cathedral founded in 1224. These are the most extensive and beautiful of ancient Scottish remains. Here are the ruins of a castle which was the residence of the earls of Moray. Elgin has iron-foundries and woollen-factories. Pop of parliamentary burgh in 1871, 7339.

El'gin, a county of Ontario, Dominion of Canada, has an area of about 700 square miles. It is bounded on the S. by Lake Erie, and partly drained by the river Thames. The soil is productive. It is intersected by the London and Port Stanley R. R. Capital, St. Thomas. Pop. 33,666.

Elgin, a city of Kane co., Ill., on Fox River, 36 miles W. by N. from Chicago, has a fine water-power and more than twenty manufacturing concerns, including a large woollen-mill, mower-and-reaper manufactory, engine and boiler works, and a wringer-factory. It is the seat of the National watch-factory, employing 1000 skilled operators, the Northern Insane Asylum, costing $500,000, and the Borden milk-condensing factory. It has an excellent academy and several fine churches. One of the chief industries is cheese and butter making in factories. Has two national banks and three newspapers, one monthly. Three railroads pass through the city—the Chicago and North-western, the Chicago and Pacific, and the Fox River R. Rs. Pop. 5441; of Elgin township, exclusive of the city, 1298.

S. L. Taylor, Ed. and Prop. "Advocate."

Elgin, a township of Plymouth co., Ia. Pop. 429.

Elgin, a post-township of Wabashaw co., Minn. Pop. 878.

Elgin (James **Bruce**), eighth earl of, born in London July 20, 1811, was educated at Oxford. He succeeded his father in 1841. This earldom was a Scottish peerage, which did not admit him into the House of Lords. He became governor of Jamaica in 1842, and of Canada in 1846. Canada prospered under his administration, which lasted eight years. He was created a peer of the United Kingdom in 1849, was sent on a mission to China in 1857, and negotiated the treaty of Tien-Tsien (1858). In 1859 he was postmaster-general, and in 1861 was appointed governor-general of India. Died Nov. 20, 1863.

Elgin (Thomas **Bruce**), seventh earl of, the father of the preceding, was born in Scotland in 1766. He obtained the rank of general in the army, and was sent as envoy extraordinary to Berlin in 1795. In 1799 he was appointed ambassador to Constantinople. He expended a large sum of money (about £50,000) in the removal of statues, bas-reliefs, and other remains of ancient art from the Parthenon and Acropolis of Athens to England. (See Elgin Marbles.) Died Nov., 1841.

Elgin Marbles, a collection of sculptures taken from the Acropolis, mainly from the Parthenon at Athens. They are so called from the earl of Elgin, who, by permission of the Porte, brought them to England, from 1808 to 1812. The government bought them in 1816 for £35,000, a little more than two-thirds of the cost of excavating and transporting them. They consist of colossal statues and pieces of statues, bas-reliefs, caryatides, bits of column, urns, etc. The marbles from the Parthenon exhibit Greek art in its highest perfection. Their influence on English art has been very great. The students of art in America have them in the form of casts. Lovers of plastic art are grateful to Lord Elgin, instead of indignant with him, for bringing within their reach these masterpieces of beauty. (See Lyon, "Outlines of the Elgin Marbles," 1816; "The Elgin Marbles from the Temple of Minerva at Athens," 1816; Lawrence, "Elgin Marbles from the Parthenon at Athens," 1818; and Ellis, "The Elgin and Phigalian Marbles," 2 vols., 1836.)

El'ginshire, a county of Scotland, is bounded on the N. by the German Ocean, on the E. by Banffshire, on the S. by Inverness, and on the W. by Nairn. Area, 473 square miles. It is divided into two separate parts by a part of Inverness-shire. The climate is mild and dry, and the soil open, sandy, and gravelly, and very fertile in the N. The chief products are wheat, oats, and other kinds of grain. It was formerly called the granary of Scotland. Here are some manufactories of woollen goods. The chief articles of export are cattle, salmon, grain, and timber. It sends, together with Nairnshire, one member to Parliament. Pop. in 1871, 43,598. Chief town, Elgin.

Elia. See Lamb (Charles).

Eli'as Levi'ta, a learned Jewish rabbi, born in 1472, was probably a native of Italy. He taught Hebrew at Rome and Venice, was distinguished as a grammarian, and published numerous works, among which are a "Hebrew Grammar," a "Chaldaic, Talmudic, and Rabbinical Lexicon," and "Massorah," containing critical notes on the text of the Bible. Died at Venice in 1549.

Eli'da, a post-village of Winnebago township, Winnebago co., Ill. Pop. 468.

Elida, a post-village of German township, Allen co., O. Pop. 533.

Élie de Beaumont (Jean Baptiste Armand Louis Léonce), a French geologist, born at Canon (Calvados) in 1798. He was educated in the Polytechnic School, and became professor of geology in the College of France in 1832, chief engineer of mines in 1833, and a member of the Institute in 1835. In conjunction with Dufrénoy he prepared a geological map of France (1841). Among his works are "Lectures on Geology" (3 vols., 1845 *et seq.*) and a "Treatise on the Mountain Systems," giving his theories on the elevation of mountain-ranges (1852). He succeeded Arago as perpetual secretary of the Academy of Sciences in 1853. Died Sept., 1874.

Elim (a "place of fountains and palm trees"), the second mentioned in the march of the Israelites after crossing the Red Sea (Ex. xv. 27). It has been identified with *Ghurundel*, about halfway between Suez and Sinai.

Elimina'tion [from the Lat. *elim'ino, elimina'tum*, to "send out" (from *e*, "out" or "out from," and *li'men, li'minis*, a "threshold" or "limit")], in mathematics, is the process of causing a quantity or letter which is common to two or more equations to disappear by framing out of the two a new equation in such a way as to omit the quantity in question. In other kinds of reasoning, not mathematical, elimination "is the extrusion of that which is superfluous or irrelevant." The term "to eliminate" is frequently but incorrectly used in the sense of "to elicit."

El'iot (Andrew), D. D., was born Dec. 28, 1718, and graduated at Harvard in 1737. He became pastor of the New North church, Boston, Mass., in 1742, and filled that position till his death, Sept. 13, 1778. He was elected president of Harvard University, but declined the honor.

Eliot (Charles William), LL.D., born Mar. 20, 1834, at Boston, Mass., educated at the Boston Public Latin School (1844–49) and at Harvard College (1849–53), was tutor in mathematics at Harvard College (1854–58), assistant professor of mathematics and chemistry (1858–61), of chemistry (1861–63), professor of chemistry in the Massachusetts Institute of Technology (1865–69), became president of Harvard College (May 19, 1869). He has published, with F. H. Storer, sundry chemical investigations, a manual of chemistry, and a manual of qualitative chemical analysis.

Eliot (George). See Evans (Marian C.).

Eliot (John), a minister of Roxbury, Mass., called "the apostle to the Indians," was born in England in 1604. He was educated at Cambridge, and came to Boston in 1631. He acquired the language of the Indians, and from 1646 he devoted himself to improving their condition and converting them to Christianity. He travelled extensively among them, enduring great privations and passing through many dangers. He succeeded in acquiring great influence over them, and many of them embraced the Christian faith. He translated the Bible into the Indian tongue (1661–63), published an Indian grammar (1666), and a number of other works, mostly relating to his missionary labors. Died May 20, 1690.

Eliot (John), D. D., an American preacher and biographer, born in Boston May 31, 1754, graduated at Harvard in 1772. With Jeremy Belknap, he founded the Massachusetts Historical Society. He was the author of a "New England Biographical Dictionary" (1809) and other works. Died Feb. 14, 1813.

Eliot (Samuel), LL.D., an American historian, born in Boston Dec. 22, 1821, graduated at Harvard in 1839. Having visited Rome and travelled in Europe, he projected a "History of Liberty," a part of which he published in 1849, two volumes, entitled "The Liberty of Rome." "The Early Christians" (2 vols., 1858) is the second part of the same work. Among his writings is a "Manual of United States History from 1492 to 1850" (1856). He was president of Trinity College, Hartford, in 1860–64.

Eliot (Samuel Atkins), a merchant of Boston, was born Mar. 5, 1798, and graduated at Harvard in 1817. He was father of President C. W. Eliot of Harvard College, was mayor of Boston (1837–39), a prominent State politician, member of Congress (1850–51), and was treasurer of Harvard College. Died Jan. 29, 1862.

Eliot (Thomas D.), born in Boston, Mass., Mar. 20, 1808, graduated with honors at Columbian College, D. C., in 1825, and was admitted to the bar. He was a Republican member of Congress (1854–69), and took a prominent part in "reconstruction" and in business relative to the freedmen after the late civil war. Died June 12, 1870.

E'lis [Gr. Ἦλις; Fr. *L'Élide*], a small state of ancient Greece in the N. W. part of the Peloponnesus, was bounded on the N. by Achaia, on the E. by Arcadia, on the S. by Messenia, and on the W. by the Ionian Sea. It is intersected by the rivers Alpheus (now *Rouphia*) and Peneus (*Gastuni*). The surface is diversified by hills and fertile plains and valleys. Elis was divided into three districts—Hollow Elis, Pisatis, and Triphylia. The chief towns were Elis, Cyllene, Pylos, and Olympia. The Olympic games, the greatest national festival of the Greeks, were celebrated at Olympia. Elis now forms with Achaia a nomarchy of the kingdom of Greece.

Elis, an ancient city, the capital of the above state, was on the river Peneus, about 10 miles from its mouth. It is mentioned as a town of the Epeii by Homer ("Iliad," ii.). It had an acropolis on a hill nearly 500 feet high, and was the only fortified town in the country. It contained several fine temples, a theatre, and the largest gymnasium in Greece. All the athletes who contended at the Olympic games were required to undergo one month's previous training in this gymnasium. When Pausanias visited Elis (about 175 A. D.) it was one of the most splendid and populous cities of Greece. The site is occupied by the modern *Paléopoli* or *Kaloscopi*.

Eli'sors. These are persons named by the court to return a jury when the sheriff and coroners are incompetent. They are two in number, and, according to Lord Coke, are named from the fact that they are *chosen* by the court (*ab eligendo*). Against their return no challenge can be taken to the array of jurors, though there may be a challenge to individual jurors or to the polls.

Eli'za, a post-township of Mercer co., Ill. Pop. 767.

Eliz'abeth, a post-twp. of Jo Daviess co., Ill. P. 1618.

Elizabeth, a post-village of Posey township, Harrison co., Ind. Pop. 216.

Elizabeth, the capital of Union co., N. J., is situated on Staten Island Sound and Elizabeth River. It has communication with New York, distant 14 miles, by three railroads—the Pennsylvania, the New Jersey Central, and the Newark and New York, which last has a branch extending to Elizabeth. It has also a line of steamboats running thither, making several trips a day. It has a horse-railroad which is about 4 miles in length. Elizabeth contains twenty-five churches, two national and four savings banks, an orphan asylum, costing $60,000, besides several other public institutions. It has three daily, one semi-weekly, and two weekly newspapers. It is remarkable for the number of New York business-men who reside here with their families, having nearly a thousand commuters who regularly travel over the roads to and from New York. Elizabeth is celebrated for the beauty of its situation and the number of its paved streets. The city, though not largely engaged in manufactures, has a number of such, which is every year increasing, the most notable of which is Singer's Sewing-machine Company, which employs 1200 hands. There are, besides, extensive oil-cloth factories and several foundries. The city has an electric fire-alarm telegraph, several parks, and is surrounded by some of the finest and richest farming country in the State. Elizabeth was formerly the capital of New Jersey, and ceased to be such in 1790. Pop. 20,832. F. W. Foote, Ed. "Daily Journal."

Elizabeth, N. C. See Elizabethtown.

Elizabeth, a township of Lawrence co., O. Pop. 3357.

Elizabeth, a township of Miami co., O. Pop. 1236.

Elizabeth, a village of Centre township, Morgan co., O. Pop. 1325.

Elizabeth, a post-borough of Allegheny co., Pa., on the right (E.) bank of the Monongahela River, 16 miles S. by E. from Pittsburg. Pop. 1196; of township, 2937.

Elizabeth, a township of Lancaster co., Pa. P. 955.

Elizabeth, a township of Wirt co., West Va. P. 804.

Elizabeth, from 1558 to 1603 the ruler of England, and the last sovereign of the House of Tudor, was born at Greenwich on the 7th of Sept., 1533. She was a daughter of Henry VIII. and Anne Boleyn. Her childhood was passed in comparative retirement, and she was educated by persons who favored the Reformed religion. She learned the Latin, Greek, French, and Italian languages of the famous Roger Ascham. In 1554 she was confined in the Tower by order of Queen Mary, who regarded her with jealousy because she was the favorite of the Protestant party. It appears that Elizabeth narrowly escaped death, and that some of the bishops and courtiers advised Mary to order her execution. After she had passed several months in the Tower, she was removed to Woodstock, and appeased Mary by professing to be a Roman Catholic.

On the death of Queen Mary (Nov. 17, 1558) Elizabeth ascended the throne, and the majority of the people rejoiced at her accession. She appointed William Cecil secretary of state, and Nicholas Bacon keeper of the great seal. She retained several Roman Catholics in her privy council, but she refused to hear mass in the royal chapel. The Protestants were the majority in the Parliament which met in 1559, abolished the mass, adopted the Thirty-nine Articles as the religion of the state, and recognized the queen as the head of the Church. "Thus," says Hume, "in one session, without any violence or tumult, was the whole system of religion altered by the will of a young woman." She declined an offer of marriage made to her by Philip II. of Spain. Her foreign policy was pacific. She waged no war for conquest, but to promote the stability of her throne she aided the Protestant insurgents in Scotland, France, and the Netherlands with money and troops. In 1563 the Parliament, anxious that she should have an heir, entreated her to marry, but she returned an evasive answer, and would neither accept the hand of any of her suitors nor decide in favor of any claimant of the throne. Among her suitors were the French duke of Anjou, the archduke Charles of Austria, and Robert Dudley, earl of Leicester, who was for many years her chief favorite. William Cecil, Lord Burleigh, was her prime minister and most trusted adviser during the greater part of her reign, the prosperity of which is ascribed to his prudence and influence.

Mary queen of Scots, fleeing from her rebellious subjects, took refuge in England in 1568, and was detained as a prisoner by Elizabeth. The latter regarded Mary as a dangerous rival, because the English Catholics wished to raise her to the throne of England, and formed several plots and conspiracies for that object. (See Mary Stuart.) Mary was beheaded Feb. 8, 1587. Philip II. of Spain had long meditated a hostile enterprise against Queen Elizabeth, who had offended him by aiding his revolted Dutch subjects and by persecuting the English Catholics. For the invasion of England he fitted out the Invincible Armada, which consisted of about 130 vessels, with over 19,000 soldiers, and sailed in May, 1588. A violent storm dispersed the Spanish ships, many of which were wrecked, and the rest were encountered by the English fleet, mostly consisting of small but excellently equipped vessels, under Admiral Howard, and thoroughly beaten, Aug. 8, 1588. The disastrous failure of this expedition did not terminate hostilities between England and Spain. An English fleet took Cadiz in 1596. After the earl of Leicester died (1588) the earl of Essex was the queen's favorite courtier. The Puritans were severely persecuted in the latter part of her reign. She died Mar. 24, 1603, and was succeeded by James VI. of Scotland, who became James I. of England. Her reign is considered one of the most prosperous and glorious in English history, and she displayed superior abilities as a ruler, but her personal character is deformed by serious faults. She was vain and selfish, and was more feared than loved by her attendants. The Elizabethan age was almost unequalled in literature, and was illustrated by the genius of Shakspeare, Spenser, Bacon, Sidney, and Raleigh. (See Froude, "History of England," vols. vii. to x.; Hume, "History of England;" Camden, "History of Queen Elizabeth," 1625; Dr. Thomas Birch, "Memoirs of the Reign of Queen Elizabeth," 1754.)

Elizabeth (Philippine Marie Hélène), a French princess, a sister of Louis XVI., was born in 1764. She was commonly styled Madame Élisabeth. In the Reign of Terror she was exposed to dangers and sufferings which she endured with fortitude. She was imprisoned in Aug., 1792, and guillotined in May, 1794.

Elizabeth'an Arch'itecture, a term applied to a style of architecture which appeared in England on the decline of the Gothic, and mostly prevailed during the reigns of Elizabeth and James I. It is sometimes called the *Tudor* style, a name more correctly applied to the Latest Gothic. It is characterized by a rich but cumbrous style of ornament, both within and without, by apartments and galleries of vast extent, and by enormous square windows. It is regarded as a debased style, and was chiefly employed in domestic architecture. Its later form is called Jacobean.

Elizabeth Christi'na, queen of Prussia, born at Brunswick Nov. 8, 1715, was a daughter of the duke of Brunswick-Wolfenbüttel. She was married to Frederick the Great in 1732. She had a high reputation for virtue and piety. Died Nov. 13, 1797.

Elizabeth City, a county in the S. E. of Virginia, at the extremity of a peninsula formed by James and York rivers. Area, about 50 square miles. It is bounded on the E. by Chesapeake Bay, and on the S. by Hampton Roads. Grain, sweet potatoes, etc. are produced. Capital, Hampton. Pop. 8303.

Elizabeth City, the capital of Pasquotank co., N. C., is situated 20 miles W. of the Atlantic, on the Pasquotank River. It has a fine harbor, safe and sufficiently deep for large vessels. A large portion of the inhabitants are of Northern origin. It has 5 churches, 2 banks, 2 hotels, 1 newspaper, 2 steam grist-mills, 4 steam saw-mills, 2 shingle-factories, and 1 planing-mill. It is surrounded by a cotton, corn, and wheat growing country, and is 50 miles S. of Norfolk, Va., with which it communicates by the Dismal Swamp Canal. It is partly in Elizabeth City and partly in Nixonton townships. Pop. 930.

PALEMON JOHN, ED. & PROP. OF "NORTH CAROLINIAN."

Elizabeth City, a post-township of Pasquotank co., N. C. Pop. 2006.

Elizabethgrad, a town of Russia, in the government of Kherson, 160 miles N. E. of Odessa. It is a military settlement, with 31,968 inhabitants.

Elizabethine Nuns, a congregation of monastic women in the Roman Catholic Church, belonging to the third order of St. Francis. The name Elizabethines was at first applied to voluntary associations of women who imitated the zeal of Saint Elizabeth of Hungary, without taking monastic vows or retiring from the world. But from the tradition that Saint Elizabeth belonged to the third order of Saint Francis, the name is sometimes given to Franciscan nuns. It is probable, however, that the Franciscan nuns of the third order were not established till 1395, long after Saint Elizabeth's death, and that their foundress was Angelina, the widow of the count de Civitelle. From 1428 to 1459 they were an independent congregation, but in the latter year were placed under the general of the Observantine Franciscans.

Elizabeth Islands, a group of sixteen small islands belonging to Dukes co., Mass., lying between Vineyard Sound and Buzzard's Bay. They constitute since 1864 the township of Gosnold. Pop. 99, principally on Cuttyhunk. The islands were once densely populated. Cuttyhunk was the seat of Bartholomew Gosnold's first colony in "Virginia," founded in 1602, but abandoned the same year, on account of troubles of the colonists with each other and with the Indians. The islands are a favorite resort for fishing and yachting. The islands, in the order of their size, are Naushon, Nashawena, Pasque, Cuttyhunk, Nonamesset, Uncatena, Penikese, and several small islets. Cuttyhunk Light, near the southern point of this group, is in lat. 41° 24.3′ N., lon. 70° 56.7′ W. One of the islands, Penikese or Pune, was presented in Mar., 1873, by John Anderson of New York, to Prof. Agassiz, for the purpose of establishing a school of natural history upon it. Mr. Anderson also gave $50,000 in money towards the endowment of the school, which is indirectly connected with the Museum of Comparative Zoology at Cambridge, Mass. The school was opened in the summer of 1873. The island contains 100 acres of land.

Elizabeth Petrov'na, empress of Russia, born in Dec., 1709, was a daughter of Peter the Great and Catherine I. She was dissolute in morals, and appears to have been unambitious, as she made little effort to obtain the throne. Ivan, an infant, was proclaimed emperor in 1740, but the French surgeon Lestocq and other partisans of Elizabeth conspired against Ivan with success, and she became empress in 1741. As an ally of Austria and France, she waged war against Frederick the Great in the Seven Years' war. Her army gained a victory at Kunersdorf, and entered Berlin in 1760. She had several children by Count Rasumovski, who was first her servant, subsequently her chamberlain, and was at length secretly married to her. She died Jan. 5, 1762, and was succeeded by her nephew, Peter III.

Elizabeth Port, a post-office in the city of Elizabeth, Union co., N. J., on Staten Island Sound, and a station on the Central New Jersey R. R., 7 miles S. of Newark and 12 miles W. S. W. of New York. It has several iron-foundries and factories, and is an important point for the shipping of coal.

Elizabeth, SAINT, of Hungary, a daughter of Andrew II., king of Hungary, was born at Presburg in 1207. She became in 1221 the wife of Louis, landgrave of Thuringia, who died in 1227 at Otranto, on his way to the Holy Land (the third crusade). His eldest brother (Henry) seized his possessions, and banished his widow and children. The knights of Thuringia restored her son Herman to the throne, and Elizabeth received as a dower the city of Marburg, where she retired with her daughters, and spent the remainder of her life in what became one continued penance. "Of all" (says Mrs. Jameson) "the glorified—victims must I call them, or martyrs?—of that terrible but poetical fanaticism of the thirteenth century, she was one of the most remarkable; and of the sacred legends of the Middle Ages hers is one of the most interesting and most instructive." She died Nov. 19, 1231. (See CHARLES DE MONTALEMBERT, "Vie de S. Elizabeth de Hongrie," 1836, which has been translated into English; also CHARLES KINGSLEY'S "Saint's Tragedy.")

Elizabeth Stuart, queen of Bohemia, a daughter of James I. of England, was born Aug. 19, 1596. She was married in 1613 to Frederick V., elector palatine, who was chosen king of Bohemia in 1619 by the Protestant party. She is said to have been beautiful, and is considered a heroine. Her husband was defeated in battle in 1620, and she passed the remainder of her life in exile and adversity. She was the mother of the famous Prince Rupert and numerous other children. Died Feb. 13, 1662. George I. of England was her grandson. (See Miss BENGER, "Memoirs of Elizabeth Stuart," 1825.)

Eliz'abethton, a post-village, capital of Carter co., Tenn., on the Watauga River, about 300 miles E. of Nashville. Pop. 321.

Eliz'abethtown, a post-village, capital of Hardin co., Ill., on the Ohio River, 90 miles above Cairo, has one newspaper-office. There are rich lead-mines in the vicinity.

Elizabethtown, a post-village of Sand Creek township, Bartholomew co., Ind., on the Jeffersonville Madison and Indianapolis R. R. (Madison division). Pop. 294.

Elizabethtown, a post-village, capital of Hardin co., Ky., on the Louisville and Nashville and Great Southern R. Rs., 42 miles S. by W. from Louisville. It is the eastern terminus of the Elizabethtown and Paducah R. R. It has one bank, eight churches, two hotels, two mills, and one newspaper. Pop. 1743.

RICHARD LA RUE, ED. AND PROP. OF "NEWS."

Elizabethtown, a post-village of Colfax co., N. M., 92 miles N. of Santa Fé.

Elizabethtown, a post-village, capital of Essex co., N. Y., on Bouquet River, about 125 miles N. of Albany. It has a court-house, jail, and weekly newspaper, and the township has extensive iron-mines and iron-works. Pop. of Elizabethtown township, 1488.

Elizabethtown, a post-village, capital of Bladen co., N. C., on Cape Fear River, 50 miles above Wilmington. Pop. 62; of Elizabethtown township, 1904.

Elizabethtown, a village of Willis township, Guernsey co., O. Pop. 44.

Elizabethtown, a village of Perry township, Licking co., O. (P. O. name, PERRYTON.) Pop. 113.

Elizabethtown, a post-borough of Lancaster co., Pa., 18 miles N. W. of Lancaster City, the county-seat, on the line of the Pennsylvania R. R., is at equal distance, 18 miles, from the county-seats of four counties—Lancaster, Dauphin, Lebanon, and York. It has 1 newspaper, 1 national bank, 4 hotels, 5 churches, a farming-implement manufactory, and a machine-shop. Principal business is farming and storekeeping. Pop. 858.

JOHN G. WESTAFER, ED. "CHRONICLE."

Elizabeto'pol, a government of Transcaucasia, is bounded on the N. by Tiflis, on the E. by Baku, on the S. by Persia, and on the W. by Erivan. Area, 17,038 square miles. The government consists in the W. of high mountains, while the E. is more level. It is drained by the Kur and numerous other small streams. Chief town, Elizabetopol. Pop. 503,282.

Elizabetopol, or **Gandscha,** the capital of the government of the same name, in Russian Transcaucasia, is situated 90 miles S. E. of Tiflis. It has a number of churches, mosques, and fruit-gardens. Silkworms are raised here. Pop. 14,971.

Eli'zaville, a post-village of Fleming co., Ky. P. 180.

Elizay, a township of Macon co., N. C. Pop. 525.

Elk (*Alces malchis*), a species of deer, is a native of the northern parts of Asia and Europe. It is one of the largest animals of the deer family or Cervidæ, is about six feet high, and sometimes weighs 1200 pounds. It has a short, compact body raised on long, stilt-like legs, a short, thick neck, and a large, narrow head, nearly two feet long. The neck is covered with a short thick mane. The antlers of the full-grown elk are flattened, displaying a broad blade with numerous snags on each horn. The tail is only four or five inches long. The color of its hair is brownish black. Elks can run with great speed. They frequent marshy districts and swampy forests, feeding on lichens, leaves, and branches of trees. Their flesh is esteemed for food.

The true American elk, commonly called the moose (*Alces Americanus*), so closely resembles the above species that

Elk or Moose.

some writers regard them as identical. But the differences are now generally considered sufficiently great to justify the opinion that the two are specifically distinct. The moose is still found in Maine and Northern New York, and north-westward. It is much hunted for its flesh and skin in winter, when the frozen crust of the snow, not strong enough to bear the animal's weight, seriously impedes its progress, its great speed at other times making its capture difficult. When brought to bay, a blow with its fore foot or horns is a serious matter for the huntsman. It is the largest known animal of the deer family now existing.

The beast generally known in America as the elk is the wapiti (*Cervus Canadensis*), an animal nearly as large as the moose. It goes in large herds, and is hunted for its flesh, and especially for its skin, which is highly prized. Several other large species of deer (as in Ceylon) or of antelope (as in South Africa) are known locally as elks. The true elks have a broad hairy muzzle, with a bald spot between the nostrils, horns large and palmated, with no basal snag; true deer have a basal snag, and more or less rounded horns; the muzzle is bare and moist.

Elk, Irish (*Megaceros Hibernicus*), the name given to a fossil deer found in the pleistocene strata, distinguished from other deer by the great size and peculiar form of its antlers. The beam of the antler is wide and flattened into a palm, and in one specimen the distance between the extreme tips was nearly eleven feet. There is a brow snag, as in the fallow deer, and also a back snag. The weight of the antlers in one specimen was eighty-one pounds. These fossils, though most abundant in Ireland, are met with in England and on the Continent.

Elk, a county in N. W. Central Pennsylvania. Area, 600 square miles. It is partly drained by Clarion River and its branches. The surface is hilly, and mostly covered with forests. Bituminous coal is found here. Lumber, grain, and wool are produced. This county is intersected by the Philadelphia and Erie R. R. Capital, Ridgeway. Pop. 8488.

Elk, a township of Clayton co., Ia. Pop. 901.

Elk, a township of Delaware co., Ia. Pop. 927.

Elk, a township of Cloud co., Kan. Pop. 561.

Elk Creek, a post-township of Grayson co., Va. Pop. 4116.

Elk Falls, a post-village, capital of Howard co., Kan., about 130 miles S. by W. from Topeka. Pop. of Elk Falls township, 1160.

Elk Fork, a township of Pettis co., Mo. Pop. 2404.

Elk Garden, a township of Russell co., Va. Pop. 2023.

Elk Grove, a post-township of Cook co., Ill. P. 1120.

Elk Grove, a post-township of La Fayette co., Wis. Pop. 1377.

El Khar'geh, a town of Upper Egypt, capital of the Great Oasis; lat. 25° 28′ N., lon. 30° 40′ E. Here are ruins of a temple and an ancient necropolis. El Khargeh is also the name of the Great Oasis itself, which is 80 miles long and 10 miles broad, and was anciently larger than at present. It abounds in acacia and doum-palm trees, and has many ruins, chiefly Macedonian and Roman. There are many warm and cold springs and a stream of water; and rice is here cultivated.

Elk'hart, a county in the N. of Indiana. Area, 467 square miles. It is drained by the Elkhart and St. Joseph's rivers, which here unite. The surface is undulating, the soil fertile. Cattle, grain, wool, hay, butter, etc. are produced, and flour, lumber, furniture, carriages, cooperage, etc. are manufactured. It is intersected by two divisions of the Lake Shore and Michigan Southern R. R. Capital, Goshen. Pop. 26,026.

Elkhart, a post-village and township of Logan co., Ill. Total pop. 1325; of village, 378.

Elkhart, a city of Elkhart co., Ind., on the Elkhart River, at the junction of the old and the air-line divisions of the Lake Shore and Michigan Southern R. R., 100 miles E. by S. from Chicago. It contains a large T-rail rolling-mill, a machine-shop, and a round-house of the railroad company. In the works are employed more than 800 men. Here are also two paper-mills, two machine-shops, three flour and two starch mills, besides other factories. The combined water-power is estimated at 8300 horse-power. The town has two banks, a school-house which cost $50,000, and four newspapers, one of which is a daily. Pop. 3265.

CHASE & KENT, PROPS. "EVENING REVIEW."

Elkhart, a township of Noble co., Ind. Pop. 1541.

Elkhart, a post-township of Polk co., Ia. Pop. 744.

Elk'horn, a township of San Joaquin co., Cal. P. 1428.

Elkhorn, a township of Brown co., Ill. Pop. 1150.

Elkhorn, a township of Warren co., Mo. Pop. 2479.

Elkhorn, a post-village of Douglas co., Neb., on the Union Pacific R. R. and on the Elkhorn River, 29 miles W. of Omaha. It is a shipping-point for grain. Pop. of township, 296.

Elkhorn, a township of McDowell co., W. Va. P. 416.

Elkhorn, a post-village, capital of Walworth co., Wis., 65 miles due N. W. from Chicago, Ill., and 45 miles S. W. from Milwaukee, is on the Western Union R. R., which connects here with the St. Paul R. R. It has a court-house, a national bank, a newspaper, a beautiful park of six acres of large oaks, 5 churches, 1 fine Union school-building, 2 hotels, and 30 stores. It is in one of the richest farming districts in the State. Pop. 1205. FRANK LELAND,

ED. AND PUB. OF "WALWORTH CO. INDEPENDENT."

Elkhorn Grove, a post-township of Carroll co., Ill. Pop. 662.

Elkhorn River, Nebraska, rises in the N. E. part of the State, flows nearly south-eastward through the counties of Madison, Stanton, Cuming, Dodge, and Douglas, and enters the Platte in the western part of Sarpy county. Length, estimated at 250 miles.

El'kins, a township of Clarke co., Ark. Pop. 584.

Elk'land, a post-township of Tuscola co., Mich. Pop. 511.

Elkland, a township of Sullivan co., Pa. Pop. 705.

Elkland, a post-borough of Tioga co., Pa. Pop. 332.

Elk Lick, a post-township of Somerset co., Pa. It includes the borough of Salisbury, on Casselman's River, the terminus of the Salisbury and Baltimore R. R. It is 25 miles N. W. of Cumberland, Md., and is the centre of the Salisbury coal-basin. It is on the proposed Transalleghany Canal, has a weekly newspaper, four churches, a shook-shop, iron-foundry, planing-mill, etc. (P. O. Elk Lick.) Pop. of Salisbury, 291; of Elk Lick township, 1012. SUHRIE & SMITH, EDS. "VALLEY INDEPENDENT."

Elk Mound, a township of Dunn co., Wis. Pop. 433.

El'ko, a county in the N. E. of Nevada, bordering on Idaho and Utah, is drained by Humboldt River. The surface is partly mountainous; the soil in some places is fertile. Silver is found here, and some grain and cattle are raised. It is intersected by the Central Pacific R. R. Capital, Elko. Pop. 3447.

Elko, a post-village, capital of the above county, is on Humboldt River and the Central Pacific R. R., 603 miles N. E. of San Francisco. It has two newspaper-offices, three large freight dépôts, a good hotel, and numerous stores; also silver smelting works and manufactures of farming tools. Here are hot mineral springs of great value for bathing purposes. Pop. of Elko township in 1870, 1160, but the population has increased largely since that time.

Elk Point, a post-village, capital of Union co., Dak., on the Missouri River, about 30 miles S. W. of Sioux City (Ia.).

Elk Prairie, a township of Jackson co., Ill. Pop. 1354.

Elk Rap'ids, a post-village, capital of Antrim co., Mich., on the east arm of Grand Traverse Bay, about 18 miles N. E. of Grand Traverse City. It has one newspaper-office. Pop. of township, 370.

Elk Riv'er, of West Virginia, flows nearly westward through Braxton and Clay counties, and enters the Great Kanawha at Charleston. Length, nearly 150 miles.

Elk River, a post-township of Clinton co., Ia. Pop. 1296.

Elk River, a village (Elk River Station P. O.) in Sherburne co., Minn., 38 miles N. W. from the capital of the State, and situated on the Mississippi and Elk rivers, with the St. Paul and Pacific R. R. running through the town. It has one newspaper, a number of stores and manufactories, a large brick school-house capable of holding 500 scholars, and four different grades of schools. Principal business, lumber, grain, and stock. It is in a good farming-region. Pop. of Elk River township, 537.

JOHN M. THOMSON, ED. "SHERBURNE CO. NEWS."

Elk Run, a township of Columbiana co., O. Pop. 1335.

Elk Run, a township of Rockingham co., Va. Pop. 2341.

Elk'ton, a post-village, capital of Todd co., Ky., about 50 miles N. W. of Nashville (Tenn.). It has three or four churches.

Elkton, a village of Washington co., Ill. Pop. 160.

Elkton, a post-village, capital of Cecil co., Md., on the Philadelphia Wilmington and Baltimore R. R., 52 miles E. N. E. from Baltimore, and at the head of navigation on the Elk River. It has a national bank, six churches, an academy and a public school, two weekly newspapers, and four hotels. There are flour, iron, and paper mills in the vicinity. Elkton was settled by the Swedes in 1694. Pop. 1797; of Elkton township, 4170.

R. C. MACKALL, ED. "DEMOCRAT."

Ell [Lat. *ulna;* Fr. *aune;* Ger. *Elle;* Dutch *el*], a measure of length adopted from the length of a man's fore arm. The English ell is 3 feet 9 inches, and the Flemish is equal to 27 inches, or three-fourths of a yard.

Ellag'ic Acid, a constituent of certain animal concretions, as the bezoar-stones of the antelope; also produced by the decomposition of gallic acid.

El'laville, a post-village, capital of Schley co., Ga., about 44 miles E. S. E. of Columbus. Pop. 157.

Ellaville, a post-village of Madison co., Fla., at the junction of the Ocopilco and Suwanee rivers, has very extensive saw-mills, with a railroad several miles long extending into the forests to supply rough timber for the mills. The village is on the Jacksonville Pensacola and Mobile R. R., 95 miles W. of Jacksonville.

El'lenboro, a post-township of Grant co., Wis. Pop. 803.

El'lenborough (EDWARD **LAW**), LORD, an able English lawyer, born in Cumberland Nov. 16, 1750. He was engaged in 1785 as the leading counsel for the defence in the trial of Warren Hastings, for whom he pleaded with success. He became attorney-general in 1801, and lord chief-justice of the king's bench in 1802. In the same year he was created Baron Ellenborough. He was a Tory in politics. Died Dec. 13, 1818.

Ellenborough (EDWARD **LAW**), EARL OF, a statesman, a son of the preceding, was born Sept. 8, 1790, and succeeded his father as baron in 1818. He was lord privy seal in 1828–29, and gained distinction as an orator in the House of Lords. In 1841 he was appointed governor-general of India, but he was recalled in 1844 by the East India Company, and then received the title of earl and viscount. He was first lord of the admiralty in 1846 for a short time in the cabinet of Peel. On the formation of a new Tory ministry in Feb., 1858, he became president of the board of control. One of his despatches censuring Viscount Canning for his conduct in India offended the public, and caused such an outcry that he had to resign in 1858. Died Dec. 22, 1871. By his death the earldom and viscounty became extinct.

El'lenburgh, a post-village and township of Clinton co., N. Y., on the railroad from Ogdensburg to Rouse's Point. The township has four churches, and manufactures of lumber, starch, leather, etc. Pop. of township, 3042.

El'len Creek, a township of Martin co., Minn. Pop. 188.

El'lendale, a township of Alexander co., N. C. Pop. 908.

El'lensburg, a post-village, capital of Curry co., Or., on the Pacific Ocean at the mouth of Rogue River, about 200 miles S. by W. of Salem.

Ellenville, a post-village of Wawarsing township, Ulster co., N. Y., 30 miles W. of the Hudson River, on the Delaware and Hudson Canal. It is the terminus of the Ellenville branch of the Midland R. R., and is situated in a beautiful and fertile valley at the foot of the Shawangunk Mountains. It is a very beautiful and thriving place. Its streets are shaded with maples. Its sidewalks are flagged at a cost of $50,000; its waterworks cost $40,000; it has many handsome public and private buildings, six churches, three weekly newspapers, graded public schools, one savings and two national banks, a glass-manufactory, cutlery-works, stoneware pottery, bluestone quarries, and manufactories of leather and boats. It has superior hotels, is a favorite summer resort, and is the seat of Ulster Seminary.

S. M. TAYLOR, ED. "JOURNAL."

El'lery, a post-township of Chautauqua co., N. Y., on Chautauqua Lake. Pop. 1616.

Ellery (WILLIAM), an American patriot, born at Newport, R. I., Dec. 22, 1727. He was a merchant in his youth, and began to practise law in 1770 at Newport. Having gained a high reputation for integrity and wisdom, he was chosen a delegate from Rhode Island to the national Congress of 1776, in which he signed the Declaration of Independence. He was re-elected, and remained in Congress until 1785. In 1790 he was appointed collector of Newport. He supported the Federal party. Died Feb. 15, 1820.

El'let (CHARLES), an American engineer, born at Penn's Manor, in Bucks co., Pa., Jan. 1, 1810. Destined by his father to the life of a farmer, his own strong brain led him to mathematical and engineering pursuits. First as a rodman, then as a voluntary, and subsequently as a paid assistant, on that great work of early American engineering, the Chesapeake and Ohio Canal, he acquired knowledge and pecuniary means to visit Europe and complete his self-education in Paris, following the course of the École Polytechnique. Subsequently an engineer on the Utica and Schenectady Railroad, then on the Erie, then chief engineer of the James River and Kanawha Canal, he was author of an "Essay on the Laws of Trade" (devoted to works of internal improvement in the U. S.) and of other works of a similar character. He shares with Roebling the honor of being a pioneer of wire suspension bridges, building in 1842 the bridge across the Schuylkill at Fairmount (on the site of the famous "Colossus" wooden bridge destroyed in 1838 by fire), "the first structure of its kind in this country, and considered at the time a triumph of engineering skill." In 1845 he affirmed that a bridge might be built across the Niagara below the Falls, secure and fitted for railroad uses; and he was in 1847 the designing and constructing engineer of the preliminary wire suspension bridge (a light foot-bridge), intended as a service bridge for the construction of the main work. Among his most noteworthy labors was his investigation of the hydraulics of the Ohio and Mississippi rivers, and his work, published by the Smithsonian Institution, he regarded as "the crowning conception of his professional career." He was among the first to advocate the use of "steam-rams," suggesting a plan to the Russian government by which to destroy the allied fleet before Sebastopol, and soon after urging the matter upon our government. He was unheeded until the event of the famous Monitor and Merrimack battle in Hampton Roads, when he was commissioned by the war department to do what he could to protect the Mississippi gun-boat squadron against a fleet of hostile rams understood to be coming up the river. He hastily equipped a fleet of nine river steamboats as "rams," of which he was given the command. In a subsequent battle (June 6, 1862), terminating in a decisive defeat of the Confederate squadron, three of their vessels were sunk outright by two of his

rams; but he received a wound, from which his already enfeebled frame rapidly gave way, and he died at Cairo, Ill., on the 21st of June. A great engineer, his power as such was worthily devoted to the maintenance of the integrity of his country, and with it his life; thus in his death uniting in one, the engineer, the soldier, the patriot.
J. G. BARNARD, *U. S. Army.*

Ellet (CHARLES RIVERS), M. D., son of the above, was born at Philadelphia in 1841. When the civil war broke out he entered the army as a surgeon, became colonel, and commanded with success a marine brigade of steam "rams," etc. on the Mississippi. Died Oct. 29, 1863.

Ellet (ELIZABETH FRIES), an American authoress, born at Sodus Point, N. Y., in Oct., 1818. Her maiden name was LUMMIS. She produced a volume of poems (1835), "Women of the American Revolution" (1848), "Summer Rambles in the West" (1853), "Queens of American Society" (1865), and numerous other works.

Ellet (WILLIAM HENRY), M. D., an American chemist, born in New York about 1804, was the husband of the preceding. He obtained a chair in Columbia College (of which he was a graduate) in 1832, and became professor of chemistry in South Carolina College in 1835. He invented a method of preparing gun-cotton. Died Jan. 26, 1859.

El'lettsville, a post-village of Richland township, Monroe co., Ind., 7 miles N. W. of Bloomington, on the Louisville New Albany and Chicago R. R. It has one private bank, two flouring-mills, one woollen-mill, four churches, two hotels, and one newspaper.
H. L. MCCOLLOUGH, ED. "REPUBLICAN."

Ellezelles, ĕl'zel', a town of Belgium, in the province of Hainaut, 16 miles N. E. of Tournay. It has manufactures of linen, a salt refinery, and breweries. Pop. 5527.

El'licott, a township of Chautauqua co., N. Y. It includes Jamestown and other villages. Pop. 6679.

Ellicott (ANDREW), an American civil engineer, born in Bucks co., Pa., Jan. 24, 1754. He founded Ellicott's Mills in Maryland, and removed to Baltimore. He was a friend of Dr. Franklin and of Washington. In 1790 he was employed by the Federal government to survey and lay out the capital of the U. S. He was appointed surveyor-general of the U. S. in 1792, and became professor of mathematics and engineering at West Point in 1812. Died at West Point Aug. 29, 1820.

Ellicott (CHARLES JOHN), D. D., since 1863 bishop of Gloucester and Bristol, was born at Whitwell, near Stamford, England, in 1819. In 1859 he was appointed Hulsean lecturer, and in 1860 Hulsean professor of divinity, at Cambridge. His commentaries on the Epistles of Saint Paul, which began to appear in 1854, have put him into the front rank of biblical scholars. His "Historical Lectures on the Life of Our Lord Jesus Christ" (1860) were the Hulsean Lectures for 1859. His first work was a "Treatise on Analytical Statics," 1842.

Ellicott City, capital of Howard co., Md., situated on the Patapsco River and the Baltimore and Ohio R. R., 10 miles from Baltimore and 31 miles from Washington. It has two newspapers, two cotton-factories, one flouring-mill, turning out 400 barrels of flour per day, one large barrel-factory, machine-shop and foundry, six churches, and three colleges, one of which is for females. Pop. 1722.
I. WOLFERSBERGER, ED. OF "PROGRESS."

El'licottville, a post-village of Cattaraugus co., N. Y., is on the Great Valley Creek, about 44 miles S. by E. from Buffalo. It has a large steam saw-mill and flouring-mill, an exchange and banking-office, two hotels, a large union school, four or more churches, and one newspaper-office. Pop. 579; of Ellicottville township, 1833.
ED. "CATTARAUGUS UNION."

El'lijay, a post-village, capital of Gilmer co., Ga., on Ellijay River, about 75 miles N. of Atlanta.

El'lington, a post-twp. of Tolland co., Conn. P. 1452.

Ellington, a township of Adams co., Ill. Pop. 2298.

Ellington, a township and post-village of Hancock co., Ia. Pop. 342.

Ellington, a post-twp. of Tuscola co., Mich. Pop. 452.

Ellington, a post-township of Dodge co., Minn. P. 258.

Ellington, a township and post-village of Chautauqua co., N. Y. Pop. of village, 314; total pop. 1556.

Ellington, a township of Outagamie co., Wis. P. 1248.

El'liot, a post-township of York co., Me., on the Portsmouth Saco and Portland R. R. It has a fire insurance company. Pop. 1769.

Elliot (GEORGE HENRY), born at Lowell, Mass., Mar. 28, 1831, graduated at West Point in 1855 as a lieutenant of artillery; served on the frontier of Texas, and in 1857 was transferred to the engineers; was engaged in the construction of fortifications on the Pacific until 1870; was a member and the engineer secretary of the lighthouse board, 1870–74, and chief engineer of the Washington aqueduct 1870–71. He was engaged in an inspection of European lighthouse systems from May to Sept., 1873, and is (1874) major and assistant to the chief of engineers at Washington, D. C.
GEO. C. SIMMONS.

El'liott, a county of Kentucky, in the N. E. part of the State. Its surface is mountainous. It is traversed by several small streams, the head-waters of the Little Sandy River. Area, about 150 square miles. Grain and tobacco are the chief products. Capital, Sandy Hook. Pop. 4433.

Elliott, a post-township of San Joaquin co., Cal. P. 954.

Elliott, a township of Louisa co., Ia. Pop. 370.

Elliott (CHARLES), D. D., LL.D., a Methodist minister, born in the county of Donegal, Ireland, May 16, 1792. He emigrated to Ohio, where he edited the "Western Christian Advocate" and other journals. He was a professor of languages at Madison College, Uniontown, Pa. (1827–31), and was president of Iowa Wesleyan University (1856–60 and 1864–67). He was the author of "A Treatise on Baptism," "Life of Bishop Roberts," "Delineation of Roman Catholicism," 2 vols. 8vo; "Sinfulness of American Slavery," "History of the Great Secession," "The Bible and Slavery," etc. Died Jan. 3, 1869.

Elliott (CHARLES LORING), an American portrait-painter, born in Scipio, N. Y., in Dec., 1812. He worked in the city of New York, and painted the portraits of several eminent men. His works are commended for fidelity of likeness. Died in Albany, N. Y., Aug. 25, 1868.

Elliott (CHARLES WYLLYS), descended from John Eliot, "the apostle of the Indians," was born in Guilford, Conn., May 27, 1817. Author of "St. Domingo" (1855), a "History of New England from the Discovery of the Continent by the Northmen in 986 to 1776" (1857), besides other works.

Elliott (CHARLOTTE), sister to the author of the "Horæ Apocalypticæ." She has written many excellent hymns; amongst others, "Just as I am, without one plea."

Elliott (EBENEZER), an English poet, called the "Corn-law Rhymer," was born near Rotherham, Yorkshire, Mar. 17, 1781. He was not liberally educated, and was considered a dull boy at school. In early youth he worked in an iron-foundry, in which his father had been employed. He produced in 1798 "The Vernal Walk," a poem. After he had worked for many years in the foundry, he married, and removed in 1821 to Sheffield, where he engaged in the iron-trade on his own account, and was successful. His most popular poems are "The Corn-law Rhymes," which promoted the repeal of the corn laws, and were much admired. He afterwards wrote "The Village Patriarch" (1829), "Byron and Napoleon" (1831), "Love," and other poems. His works are commended for their energy and the sympathy with the poor which they exhibit. Died Dec. 1, 1849.

Elliott (EDWARD BISHOP), an English clergyman, was born about 1795, and educated at Cambridge. He is best known as author of the "Horæ Apocalypticæ," 4th ed. 1851; 5th ed. 1862.

Elliott (EZEKIEL BROWN) was born in Sweden, Monroe co., N. Y., July 16, 1823, and graduated at Hamilton College in 1844. He was for some years a teacher, and afterwards was for a time superintendent of certain telegraph lines, and later (1855–56) an actuary in a life insurance company in Boston, Mass. In 1861 he became actuary of the U. S. Sanitary Commission. In 1863 was a member of the International Statistical Congress at Berlin. In 1865 he became secretary of the commission for revising the U. S. revenue laws. In 1871 he entered the civil service reform commission. Mr. Elliott is the author of a number of important papers, among which are the following: Life, annuity, and other useful tables involving quantities depending on the duration of life, with discussions of the principles underlying different methods of construction, based on Prussian, English, Belgian, Massachusetts, and other data, and published with the proceedings of the American Association for the Advancement of Science at its sessions in Albany, 1856, and in Montreal, 1867; a statistical report to the Sanitary Commission, made in 1862, on the mortality and sickness of the U. S. volunteers: a memoir on the "Military Statistics of the United States," published in connection with the proceedings of the International Statistical Congress at its fifth session, held at Berlin in 1863; a second table of Prussian mortality, prepared in 1864 and published in the "Zeitschrift" of the Royal Statistical Bureau of Prussia; "Tables of the Money, Weight, and Measure of the Principal Commercial Countries in the World," published in the appendix to "Webster's Counting-house Dictionary," ed. 1868; "Letters to the Secretary of the Treas-

ury on the Credit of the U. S. Government, as indicated by the Market-prices of its Securities," published in 1871 and 1872; life and annuity tables, based on the returns of the U. S. census of 1870, in comparison with corresponding data for other countries, with an analysis of the method of construction, prepared for the superintendent of the census, and published in the second volume of his report—that on vital statistics.

Among other papers prepared by Mr. Elliott may be named: in 1850, a demonstration of the principle that from a single voltaic battery may be simultaneously supplied, without sensible interference, the voltaic current for several telegraphic conducting wires; in 1860, a discussion, by quaternions, of the law which governs mutual action of elements of electric currents, resulting in a modification of the usually accepted formula of Ampère; in the same year, a memoir on the calculus of affected quantities of the second order (quaternions); several communications, in 1869, 1870, and 1871, on the simplification of international coinage; and one, in 1872, on the relation obtaining between the frequency of auroras and the periodical lengthening and shortening of the sun's radius-vector.

Elliott (Jesse Duncan), an American commodore, born in Maryland July 14, 1782. He gained the rank of lieutenant in 1810, and was second in command under Com. Perry at the battle of Lake Erie, in Sept., 1813. Congress voted him a gold medal for his conduct in this action. He became a captain in 1818. Died Dec. 10, 1845.

Elliott (Jonathan) was born in England in 1784, emigrated to the U. S. about 1802, and fought in New Granada under Bolivar. In 1814 he went to Washington, where he was for thirteen years editor of the "Washington Gazette." He was author of "The American Diplomatic Code" (1827) and other works. Died Mar. 12, 1846.

Elliott (Stephen), LL.D., an American naturalist, born at Beaufort, S. C., Nov. 11, 1771, graduated at Yale College in 1791. He was professor of natural history in the medical college at Charleston, and president of the Bank of South Carolina. He wrote for the "Southern Review," and published "The Botany of South Carolina and Georgia" (2 vols., 1821–24), a work of merit. Died Mar. 28, 1830.

Elliott (Stephen), D. D., son of the preceding, and professor of sacred literature in South Carolina College, was born at Beaufort, S. C., Nov. 13, 1805. He became bishop of Georgia in 1841. Died Dec. 21, 1866.

Elliott (Stephen, Jr.), a brigadier-general in the Confederate army, born at Beaufort, S. C., 1832. On the outbreak of the civil war he organized and equipped the battery known as the Beaufort Artillery. He commanded at Pinckney Island Aug., 1862, and was promoted for gallant conduct; was in command of Fort Sumter during the protracted bombardment to which it was subjected; and in 1864 was severely wounded by the mine explosion near Petersburg, which incapacitated him from further active service for the remainder of the war. In 1865 he subscribed to the oath requiring him to support the Constitution of the U. S. and his own State. Received the nomination for Congress. Died at Aiken, S. C., Mar. 21, 1866.

Elliott (Washington L.). See Appendix.

Elliott (William) was born at Beaufort, S. C., April 27, 1788. He was a member of the legislature of that State, and opposed nullification in 1832. He wrote against secession about 1851, and was the author of "Fiesco," a tragedy (1850). Died in Feb., 1863.

El'liottsville, a township of Shelby co., Ala. Pop. 501.

Elliottsville Plantation, a township of Piscataquis co., Me. Pop. 42.

Ellipse [Gr. ἔλλειψις, "omission" or "defect," so called because the square of the ordinate is less than, or differs in defect from, the rectangle under the parameter and abscissa], a hypotrochoid curve of the second order, one of the conic sections, found by cutting a cone by a plane passing obliquely through the opposite side of the cone. If two fixed points be taken in a plane, and a third point be conceived to move around the two fixed points in such a way that the sum of the distances of the moving point from the fixed point shall always be the same, the moving point will describe an ellipse. The fixed points are the foci of the ellipse, and a point in the same straight line with the foci, and equally distant from each, is the centre. That axis of the ellipse which passes through the foci is the transverse or major axis; an axis perpendicular to the transverse is the conjugate or minor axis.

If a moving circle roll along the concavity of the circumference of a fixed circle in the same plane, the radius of the former circle being half that of the latter, any given point in the plane of the rolling circle, within or without, will describe an ellipse. Various instruments for marking the ellipse have been devised on this principle.

El'lis, a county in W. Central Kansas. Area, 900 square miles. It is intersected by Saline and Smoky Hill rivers, branches of the Kansas. The surface is nearly level, and is mostly prairie-land, well suited for stock-raising. It is traversed by the Kansas Pacific R. R. Capital, Hays City. Pop. 1336.

Ellis, a county in N. Central Texas. Area, 1000 square miles. It is bounded on the N. E. by the Trinity River. It contains fertile rolling prairies and forests of hard timber. Cattle, fruit, wool, corn, cotton, and swine are raised. It is intersected by the Houston and Texas Central R. R. Capital, Waxahachie. Pop. 7514.

Ellis, a township of Hardin co., Ia. Pop 518.

Ellis (George Edward), D. D., a Unitarian minister and author, born in Boston Aug. 8, 1814, graduated at Harvard in 1833. He was ordained pastor at Charlestown about 1838. He wrote for Sparks's "American Biography" lives of William Penn and others. In 1857 he became professor of theology in the Divinity School at Cambridge. Among his works is a "Half Century of the Unitarian Controversy" (1857).

Ellis (Harvey W.) was born in Kentucky. He settled in Tuscaloosa, Ala., where he was repeatedly elected to the legislature of that State. He died in 1842.

El'lisburgh, a post-village and township of Jefferson co., N. Y. The township is on Lake Ontario, is traversed by the Rome Watertown and Ogdensburg R. R., and has some manufactures. There is an academy at Belleville. This township is one of the wealthiest in the State. There was an engagement here in 1814 between the Americans and a superior British force. The latter were defeated. Pop. of township, 4822.

El'lison, a post-township of Warren co., Ill. P. 1258.

El'lis Station, a post-tp. of Ellis co., Kan. Pop. 120.

El'lisville, a post-township of Fulton co., Ill. P. 657.

Ellisville, a post-village, capital of Jones co., Miss., on the Tallahalla River, 144 miles S. E. of Jackson.

Ellore, ĕl'lōr', a town of India, presidency of Madras, 38 miles N. of Masulipatam, is a British military station. It is reported to be populous. The climate is unhealthy.

Ellora, Hindostan. See Elora.

Ells'worth, a county in Central Kansas. Area, 720 square miles. It is intersected by the Smoky Hill Fork of the Kansas River. The surface is nearly level, and is generally fertile. Cattle and grain are raised and coal is found. It is traversed by the Kansas Pacific R. R. Capital, Ellsworth. Pop. 1185.

Ellsworth, a township of Emmet co., Ia. Pop. 98.

Ellsworth, a township of Hamilton co., Ia. Pop. 186.

Ellsworth, a post-village, capital of Ellsworth co., Kan., is on the Kansas Pacific R. R., 223 miles from Kansas City and 415 miles from Denver. It is one of the leading markets for Texas cattle in the State, not less than 150,000 head being distributed from this point every year. It has a bank, a newspaper, five hotels, and a brick schoolhouse costing $20,000. The country adjoining is unsurpassed for grazing. Pop. of Ellsworth township, 448.

G. A. Atwood, Ed. "Reporter."

Ellsworth, a port of entry and capital of Hancock co., Me., on the navigable Union River, 2 miles from its mouth and 30 miles S. E. of Bangor. Several bridges cross the river here. Its trade is considerable, and its main industries are lumbering, shipbuilding, and cooperage. It has fifteen saw-mills, two steam-mills, a savings-bank, five churches, a public library, and one newspaper. Pop. of township, 5257.

A. F. Drinkwater, Ed. "American."

Ellsworth, a township of Mecker co., Minn. P. 270.

Ellsworth, a post-township of Nye co., Nev. P. 54.

Ellsworth, a post-twp. of Grafton co., N. H. Pop. 193.

Ellsworth, a post-village of Pierrepont township, St. Lawrence co., N. Y., on Racket River. Called also East Pierrepont. Pop. 179.

Ellsworth, a post-twp. of Mahoning co., O. Pop. 652.

Ellsworth, a township of Tyler co., W. Va. P. 1890.

Ellsworth, a post-village, capital of Pierce co., Wis., 40 miles S. E. of St. Paul, Minn., has a steam saw-mill, stave-mill, three hotels, and one newspaper. Pop. of township, 747.

M. B. Kimball, Ed. "Herald."

Ellsworth (Ephraim Elmer), an American officer, born in Mechanicsville, Saratoga co., N. Y., April 23, 1837, became a resident of Chicago. He organized a well-disciplined body of Zouaves before the civil war, and in Mar.,

1861, he escorted President Lincoln to Washington. In April he became colonel of a Zouave regiment of New York firemen. When the government troops (May 24, 1861) took possession of the shores of the Potomac (including the city of Alexandria) opposite Washington, to Col. Ellsworth's regiment was assigned the seizure and occupation of that city. Observing a secessionist flag flying over the "Marshall House" (a hotel kept by one Jackson), he ascended to the roof himself and took it down. Descending with it in his hand, he was met and shot dead by the innkeeper, who immediately encountered a similar fate from the attendant soldiers.

Ellsworth (HENRY LEAVITT), born at Windsor, Conn., Nov. 10, 1791, graduated at Yale in 1810, and studied law at Litchfield. He resided mostly in Connecticut, but was for some time a resident commissioner of the U. S. with the South-western Indians, and from 1845 to 1857 lived in Lafayette, Ind. He was (1836–45) U. S. commissioner of patents. He published a series of valuable agricultural reports from the patent office; also a "Digest of Patents" (1840). Died Dec. 27, 1858.

Ellsworth (OLIVER), LL.D., chief-justice of the U. S., was born in Windsor, Conn., April 29, 1745, and graduated at Princeton in 1766. He studied law, was admitted to the bar in 1771, and elected a delegate to the Continental Congress in 1777. In 1784 he was appointed a judge of the superior court, and in 1787 was a member of the convention which framed the Federal Constitution. Having joined the Federal party, he was elected in 1789 to the Senate of the U. S., in which he gained distinction as a debater and supported Washington's administration. He was appointed chief-justice of the Supreme Court by Washington in 1796. In 1799 he was sent as envoy extraordinary to Paris, where he and his colleagues negotiated a treaty with France. He resigned the office of chief-justice in 1800. Died Nov. 26, 1807.

Ellsworth (WILLIAM WOLCOTT), LL.D., was born at Windsor, Conn., Nov. 10, 1791, and graduated at Yale in 1810, became a lawyer, was professor of law in Trinity College, Hartford, Conn. (1827–68), member of Congress (1829–33), governor of Connecticut (1838–42), and a justice of the State supreme court (1847–61). Died at Hartford Jan. 15, 1868.

Ell'wangen, a town of Würtemberg, on the Jaxt, 45 miles E. N. E. of Stuttgart. It has a cathedral, a castle, a hospital, and a gymnasium; also tanneries and bleachworks. Pop. in 1867, 3895.

Ell'wood (THOMAS), an English writer, born in Oxfordshire in 1639, was a minister of the Society of Friends. His friend Isaac Penington procured for him in 1662 the position of reader to the poet Milton, who was then blind and lived in London. "I went," says Ellwood, "every day in the afternoon (except on the first days of the week), and sitting by him in his dining-room, read to him in such books in the Latin tongue as he pleased to hear." After he had passed six weeks in this occupation, Ellwood went to the country for the sake of his health, which was impaired. He visited Milton at Giles-Chalfont in 1665, when the poet showed him the manuscript of "Paradise Lost," and requested him to take it home and read it. On returning the manuscript, Ellwood suggested to Milton the idea of "Paradise Regained," by asking, "What hast thou to say of Paradise Found? He made no answer, but sat some time in muse." Among Ellwood's works are a "Sacred History" (1705), a poem called "Davideis" (1712), and "Memoirs of his own Life" (1714). Died Mar. 1, 1713.

Elm [Lat. *ul'mus;* Ger. *Ul'me;* Fr. *orme*], a genus of trees of the order Ulmaceæ, natives of Europe and North America, with alternate serrate leaves, which are oblique or unequally heart-shaped at the base. The ovary is 2-celled, with a single anatropous ovule. The fruit is a 1-celled membranaceous samara, winged all round. This genus comprises numerous species, five or more of which are indigenous in the U. S. The most remarkable of these is the *Ul'mus America'na* (white or American elm), a large ornamental tree, usually with spreading branches and drooping, pendulous boughs. It grows rapidly, often attains the height of 100 feet, and is considered one of our most noble and beautiful forest trees. Its favorite habitat is in moist woods where the soil is rich, and in the vicinity of rivers and creeks. The trunk sometimes ascends without branches fifty or sixty feet, and then separates into a few primary limbs, which gradually diverge and present long arched pendulous branches floating in the air. The wood of this tree is used for making hubs of wheels. Another species native of the U. S. is the slippery elm (*Ul'mus ful'va*), a smaller tree with a very mucilaginous inner bark, which is used in medicine as a demulcent. Among the important trees of this genus is the common English elm (*Ulmus campestris*), which grows in many parts of Europe, and is extensively planted in Great Britain. It is one of the chief ornaments of English scenery. The wood of this tree is compact, fine-grained, very durable in water, and is used for various purposes by wheelwrights, machinists, joiners, and shipbuilders. It has a mucilaginous bark, which is esteemed as a medicine. The *Ul'mus monta'na,* or wych elm, is a native of Scotland, and a tree of rapid growth, valuable for timber, which is used for the same purposes as the English elm. Europe also produces the cork-barked elm (*Ul'mus subero'sa*), a tall tree extensively planted in England, and named with reference to the corky ridges or wings on its branches. A valuable fine-grained wood is obtained from the *Ul'mus ala'ta,* winged elm or wahoo, which grows wild in the Southern U. S., and has corky-winged branches.

Elm, a township of Wayne co., Ill. Pop. 968.

Elm, a township of Putnam co., Mo. Pop. 1640.

El'ma, a township and post-village of Erie co., N. Y. It has important manufactures. P. 165; of township, 2827.

Elm Creek, a township of Saline co., Kan. Pop. 2027.

Elmendaro, a post-township of Lyon co., Kan. P. 533.

El'mer, a post-village of Pittsgrove township, Salem co., N. J. It is a station on the West Jersey R. R., 26 miles S. of Philadelphia, and at the junction of the branch railroad to Salem, N. J. Pop. 347.

Elmer (LUCIUS Q. C.), LL.D., born at Bridgeton, N. J., in 1793, graduated at Princeton in 1824, was a prominent lawyer and State politician, a member of Congress from New Jersey (1843–45), attorney-general of the State (1850–52), and a judge of the State supreme court (1852–59). He published a "Digest" of New Jersey laws (1838).

Elm Grove, a township of Tazewell co., Ill. P. 1072.

Elm Grove, a township of Louisa co., Ia. Pop. 701.

Elmi'na, a fortified town and seaport of Africa, the former capital of the Dutch possessions on the Guinea coast, is in lat. 5° 5′ N., and lon. 1° 23′ W. It is defended by a strong fort. Elmina was taken from the Portuguese by the Dutch in 1637. Pop. estimated at 15,000. On April 6, 1872, it was ceded, with the Dutch possessions in Guinea, to Great Britain. In 1873 it was burned by the British troops on account of its sympathy with Ashantee.

Elmi'ra, a post-village of Woolwich twp., Waterloo co., Ontario, Canada, 12 miles from Berlin, the county-seat. It has factories and mills, and one weekly newspaper. P. 850.

Elmira, a post-township of Stark co., Ill. Pop. 1108.

Elmira, a township of Olmsted co., Minn. Pop. 1055.

Elmira, a city, the capital of Chemung co., N. Y., at the crossing of the Erie and Northern Central R. Rs., 274 miles by rail N. W. by W. of New York. The Chemung Canal extends to Seneca Lake, and the Junction Canal connects Elmira with the interior of Pennsylvania. It is on the Chemung River, and is the largest city in that part of the State. There is one rolling-mill and one blast-furnace, each with $1,500,000 capital, and in full operation; one woollen-mill, ten shoe-and-boot factories, three iron-foundries, a manufactory of steam fire-engines, besides machine-shops and other like industries, including the large shop of the Pullman Car Company for the manufacture and repair of cars. The large shops of the Erie R. R. and the principal shops of the Northern Central R. R. are situated here. There are 19 churches—5 Roman Catholic, 2 Episcopal, 2 Presbyterian, 3 Baptist, 3 Methodist, 1 Congregational, and 3 colored. The State Reformatory, now in process of erection, will be an imposing structure. The Elmira Female College (Presbyterian) is large and well endowed. The public-school system is excellent. Many of the school-houses are very fine. Eldridge Park, containing over 300 acres, was established by private enterprise, and is finely laid out. The city has a fine court-house, a jail, a water-cure, a surgical institute, an orphans' home, etc. There are two State, one national, one private, and one savings bank, two daily and two weekly newspapers, a steam fire department, street railways, and water-works with a storing reservoir holding 120,000,000 gallons of water. The future of the city is full of promise. Its trade with the surrounding country is very extensive. The township, outside of the city, is very fertile and has several stone-quarries. The city was incorporated in 1865. It was during the late civil war a great recruiting rendezvous, and immense barracks were erected here, which have since been removed. It was also the site of a military prison, where many Confederate prisoners were confined. Pop. of city, 15,873; of township, exclusive of city, 1190.

AUSBURN TOWNER, LOCAL ED. "ELMIRA ADVERTISER."

El Mon'te, a township of Los Angeles co., Cal. P. 1254.

El'more, a county in E. Central Alabama. Area, 775 square miles. It is bounded on the E. and S. by the Tallapoosa River, and intersected by the Coosa. These rivers

unite on the southern border of this county to form the Alabama River. The soil is productive. Grain, cotton, and wool are raised. The S. and N. Alabama R. R. passes through the south-western part. Cap. Wetumpka. P. 14,477.

Elmore, a township of Daviess co., Ind. Pop. 865.

Elmore, a post-township of Faribault co., Minn. P. 470.

Elmore, a post-village of Harris township, Ottawa co., O., on Portage River, 20 miles from Lake Erie, and on the southern division of the Lake Shore and Michigan Southern R. R., 16 miles S. E. of Toledo. It has one bank, eight churches, two hotels, and one newspaper. Pop. 1131.

J. E. Crofoot, Ed. "Courier."

Elmore, a post-township of Lamoille co., Vt. It has manufactures of lumber and starch. Pop. 637.

Elmore (Franklin Harper), an American lawyer and financier, born in South Carolina in 1799. He became a member of Congress in 1837, and president of the Bank of the State of South Carolina in 1840. He was elected to the U. S. Senate in 1850, and died May 29 of the same year.

Elmore (Rush), a son of Gen. John Elmore, was educated for the bar, served in the Mexican war, and was, in 1854, by President Pierce, appointed a judge of the U. S. court in Kansas. He died during the war.

El'mo's Fire, Saint [*Elmo* is an Italian form of the name *Elijah*], an electrical light which at sea sometimes attaches itself to the ends of masts and spars. When two such lights are seen it is called Castor and Pollux, and is considered by sailors a sign of fair weather and good luck; one ball of light, called Helena, is regarded as a bad omen.

Elms'horn, a town of Germany, in the Prussian province of Sleswick-Holstein, on the river Krückau and on the Kiel and Altona Railway, about 22 miles N. W. of Hamburg. It has an active trade in grain and manufactures of shoes, etc. Pop. in 1871, 4832.

Elm Spring, a township of Washington co., Ark. P. 1071.

Elm'wood, a post-village of Peoria co., Ill., on a branch of the Chicago Burlington and Quincy R. R., 163 miles S. W. of Chicago. It has one newspaper office. Pop. 1476; of Elmwood township, including village, 2110.

Elmwood, a township of Leelenaw co., Mich. P. 535.

Elmwood, a township of Tuscola co., Mich. P. 369.

Elmwood, a post-township of Saline co., Mo. P. 1538.

Elmwood, a post-township of Cass co., Neb. P. 317.

Éloge, ā'lozh', a French term signifying "eulogy," is applied in France to the panegyrical orations pronounced in honor of eminent deceased persons, and particularly of members of the French Academy and Institute. The duty is now performed by the new member elected as the successor of the deceased. Fontenelle was one of the first who excelled in this species of composition.

E'lon, a township of Amherst co., Va. Pop. 3193.

Elonga'tion [from the Lat *e*, "out," and *lon'gus*, "long"], in astronomy, is the apparent angular distance of a planet from the sun. The greatest elongation of Mercury amounts to about 28° 30′, that of Venus to about 47° 48′, and that of the superior planets may have any value up to 180°.

El'oquence [Lat. *eloquentia*; *e*, "out," and *loquor*, to "speak"] is the expression of thought or emotion in such a manner as to produce conviction or corresponding emotion in others. The term was originally applied to public speaking alone, but the rules for that art being generally applicable to writing, it was used in a wider sense. In Greece in the age succeeding Pericles arose a school of rhetoricians, who sought to graft upon eloquence the subtleties of logic. Gorgias and Isocrates belonged to this school, and in this age Grecian eloquence attained its highest perfection in Demosthenes. Soon after this it declined rapidly, and the names of Athenæus and several others have been preserved from oblivion chiefly by the writings of Longinus. When the liberal arts began to flourish at Rome by the exertions of Greeks, the senate in the year of the city 592 decreed the banishment of all rhetoricians. But the Romans a few years later were so charmed with the eloquence of Carneades, Diogenes, and Critolaus, the ambassadors from Athens to Rome, that they made the study of oratory part of a liberal education. It made the most rapid progress, and was at last crowned by the appearance of Cicero. From his writings we learn that many great orators existed at Rome before the age of Augustus. The despotic character of the government in succeeding ages checked the growth of the art, which quickly declined. The history of eloquence in England records the names of Pitt, Burke, Fox, Sheridan, and others of the first eminence. The statesmen of Ireland have as a class been remarkable for their excellent oratory. In Germany there has been so little opportunity for the display of forensic or senatorial eloquence that its growth has been in a measure checked; and the same may be said of Spain, Italy, and Portugal, which, however, have been rich in pulpit eloquence. The French language is essentially a colloquial one, but the great names of Bossuet, Bourdaloue, Massillon, Lacordaire, Lamennais, and Hyacinthe illustrate its capabilities for pulpit oratory, while the Revolution brought out many powerful public speakers in politics. Of these Mirabeau is the most celebrated. In the U. S. public speaking is one of the great social powers, and it is accordingly cultivated with assiduity and success.

Of the earlier American orators, Fisher Ames was perhaps the most finished. The "great triumvirate," Webster, Clay, and Calhoun, in public affairs, Wirt and Choate at the bar, and Samuel Davies, John Mason, and not a few other pulpit-orators, have attained great eminence. The names of Everett and Wendell Phillips also deserve mention.

Elo'ra, or **Ellora,** a decayed town of Hindostan, near Dowlatâbâd; lat. 20° 5′ N., lon. 75° 13′ E. Here are numerous remarkable cave-temples, which surpass in magnitude all others in India, and are adorned with statues and other sculptures. Besides the cave-temples hewn out in the slope of a rocky hill, there are vast edifices or pagodas carved out of solid granite hills, so as to form magnificent monoliths, having an exterior as well as interior architecture, richly decorated. They are among the most stupendous monuments ever raised by man. The most remarkable of these is the temple called *Kailasa*, which is about 145 feet long and 100 feet high, and is supported by four rows of pilasters with colossal elephants beneath. In the court which surrounds the temple of Kailasa are several obelisks, sphinxes, and colonnades. Many mythological figures are carved on the walls. The date of the construction of these temples is not known. According to Mr. Fergusson, they were executed not later than 200 B. C. (See Fergusson, "Handbook of Architecture.")

Elo'ra, a post-village of Ontario, Dominion of Canada, in Wellington county and on Grand River at its falls, 12 miles N. W. of Guelph, on the Wellington Grey and Bruce Railway. It has two newspapers, a large trade, and extensive manufactures. Pop. in 1871, 1498.

El Pa'so, ĕl pä'so (*i. e.* "the passage" or "gap"), a county in the central part of Colorado, has an area of about 2600 square miles. It is drained by several small affluents of the Arkansas River. The western part is mountainous, the eastern a broken plain. The highest point of this county is Pike's Peak, which rises 11,497 feet above the level of the sea. It abounds in grand scenery. Stock-raising and lumber-cutting are the chief industrial pursuits. Grain, wool, and dairy products are the agricultural staples. It is intersected by the Denver and Rio Grande R. R. Capital, Colorado City. Pop. 987.

El Paso, a county which forms the W. extremity of Texas, is bounded on the S. W. by the Rio Grande, which separates it from Mexico. The surface is mostly sandy plains, but some parts are very mountainous. There are several salt-lakes with no outlets. Wine, salt, and fine onions are exported. Silver ore abounds. The county contains many Mexicans and Pueblo Indians. Area, 9450 square miles. Capital, El Paso. Pop. 3671.

El Paso, a city of Woodford co., Ill., on the Illinois Central R. R. where it crosses the Toledo Peoria and Warsaw R. R., 17 miles N. of Bloomington and 33 miles E. of Peoria. It has one newspaper-office. A coal-shaft is now going down. Two large mills, five grain-elevators, one carriage-manufactory, and two agricultural-implement works are among the business industries of the place. Pop. 1564, or, including El Paso township, 2416.

E. T. Baldwin, Ed. "Journal."

El Paso, a post-village, capital of El Paso co., Tex., on the Rio Grande, near lat. 31° 42′ N. Near this place the river passes through a gap or gorge in a mountain called El Paso del Norte ("North Pass"), which is the chief thoroughfare between Mexico and New Mexico.

El Paso, a post-township of Pierce co., Wis. Pop. 248.

El Pa'so del Nor'te ("the pass of the north"), a fertile valley in the Mexican state of Chihuahua, on the Rio Grande, about 350 miles S. by W. from Santa Fé. Here are produced wine and brandy, which are called Pass wine and Pass brandy.

Elphinstone (Hon. Mountstuart), a British historian, born in 1778, was a younger son of Lord Elphinstone. He was sent as ambassador to the court of Cabool in 1808, and became governor of Bombay in 1819. Bishop Heber expressed the opinion that he was "in every respect an extraordinary man," and that his Indian policy was wise and liberal. Mr. Elphinstone resigned in 1827, and returned to

England. He published an "Account of the Kingdom of Cabool" (1815) and a "History of India: the Hindoo and Mohammedan Periods" (2 vols., 1841), both of which are highly esteemed. Died Nov. 20, 1859.

El Rosar'io, a town of the Mexican state of Cinaloa, 55 miles E. of Mazatlan. Here were rich gold-mines, which are no longer worked. It is an entrepôt of trade between Mazatlan and the interior. Pop. 5000.

Elroy, a post-village of Juneau co., Wis. It is the S. E. terminus of West Wisconsin R. R., at its junction with Chicago and North-western R. R., 210 miles N. E. of Chicago, and has a seminary and 1 weekly newspaper.

Elsass [*i. e.* "the country of the 'Sassen' (settlers) on the Ill;" Lat. *Alsatia;* Fr. *Alsace*], a German country, bounded on the E. by the Rhine, on the S. by Switzerland, and on the W. by the Vosges Mountains, which separate it from France. Area, about 3350 square miles. It was ceded to France by the emperor of Austria in 1648, and became a province of that country. After the division of France into departments, about 1790, it formed the departments of Haut Rhin and Bas Rhin (Upper and Lower Rhine), which in 1866 contained a population of 1,119,255. Chief towns, Strasburg, Colmar, and Mülhausen. After the German armies had defeated and captured Napoleon III. in 1870, Bismarck and his king insisted on the annexation of Elsass to Germany as one of the conditions of peace. The French therefore continued to fight for it, but at last they were compelled to cede it (with the exception of the fortress Belfort and its *rayon*) by the treaty of May 10, 1871. The total population, according to the census of 1871, was 1,059,279, a decrease of about 60,000 since 1866.

Elsasser (F. A.), a German landscape-painter, born in 1810, went to Italy in 1832, where he lived chiefly in Rome. Italian history and scenery form the subjects of his most celebrated works, among which are "The Campo Santo near Pisa by Moonlight," "The Siren Grotto in Tivoli," and "The Imperial Palace in Rome." Died in 1845.

Elsass-Lothringen [Fr. *Alsace-Lorraine*], the name of a new German country formed of those portions of Alsace and Lorraine which in 1871 were ceded by France to Germany. It has not been annexed to any particular German state, but it is a Reichsland (imperial land), immediately subject to the emperor. Area, 5596 square miles. It is divided into three districts (Bezirke)—Ober-Elsass, Unter-Elsass, and Lothringen. The first corresponds to the former French department of Haut Rhin, the second to the former French department of Bas Rhin, while the third contains all the territory which has been ceded of the French departments of Moselle, Meurthe, and Vosges. The districts have been subdivided into circles (Kreise), which in extent do not correspond to the former French arrondissements. Ober-Elsass contains seven, Unter-Elsass eight, and Lothringen eight circles. Pop. 1,549,459.

It is estimated that about six-sevenths of the population (about 1,340,000) speak the German language, and 210,000 French. Of the latter, 180,000 belong to Lothringen, and 15,000 to Ober-Elsass and Unter-Elsass each. About 81 per cent. of the population belongs to the Roman Catholic religion, which in Elsass-Lothringen is more predominant than in any other German state; Bavaria, the next in order, numbering only 71 per cent. of Catholics. The legislative functions are exercised by the German Reichstag, in which Elsass-Lothringen will, until Jan. 1874, not be represented. At the head of the administration is an Oberpräsident, who is subordinate to the imperial chancellor; the imperial chancery has a special division for the affairs of Elsass-Lothringen. The revenue and expenditure amounted for 1872 to 45,142,991 francs each. The new country is as yet without a public debt. At the time when the country was ceded to Germany 770 kilometers (1 kilometer = 0.62 English miles) of railroads were in operation, which, with a few exceptions, belonged to the Société des Chemins de Fer de l'Est, from which the German empire bought them for 325,000,000 francs. The navigable rivers are the Rhine, Ill, Moder, Saar, and Moselle. The soil is fertile, and rich in mines of iron, copper, and coal. The chief productions of the soil are grain, wine, beet-root, tobacco, madder, and linseed. Mülhausen (Mulhouse) is the seat of important manufactures of cotton prints, muslins, flowered silk stuffs, linen damasks, etc. Capital, Strasburg.

El-Seewah (anc. *Ammonium*), the most northerly of the five Egyptian oases, about 440 miles W. N.W. of ancient Thebes. It is six miles long and three broad. The oasis abounds in salt and alum, which were anciently exported in great amount. Dates, pomegranates, and other fruits are produced in surprising quantities. Sheep and cattle are bred in great numbers. It abounds in fresh-water springs, and is in part rather marshy. The ruins of the temple of Ammon and of other ancient buildings are still in existence. Pop. about 8000. Chief town, Kebir.

Els'heimer (Adam), a skilful German landscape-painter, born at Frankfort-on-the-Main in 1574, was called Il Tedesco (*i. e.* "the German") by the Italians. He worked in Rome, where he died in 1620. His works are highly finished. He excelled in chiaroscuro.

El'sie, a post-village of Clinton co., Mich., has one monthly publication.

El'sinborough, a township of Salem co., N. J. Pop. 700.

Elsinore [Dan. *Helsingör*], an old and interesting town and seaport of Denmark, is on the island of Seeland and on the western shore of the Sound (here only 2½ miles wide), 24 miles N. by E. of Copenhagen; lat. 56° 2′ N., lon. 12° 37′ E. It is defended by the castle of Kronborg, which commands the Sound at its narrowest part. It has a cathedral, a custom-house, and a royal palace called Marienlist, from which is obtained a magnificent view of the Sound and of Helsingborg in Sweden. At Elsinore the Sound dues were formerly collected from foreign vessels navigating the Sound. It has an active trade, and some manufactures of arms, brandy, hats, etc. Here was laid the scene of Shakspeare's "Hamlet." Pop. in 1870, 8891.

Elsinore, a post-township of Allen co., Kan. P. 452.

El'ssler (Fanny), a German dancer, born at Vienna in 1811. She performed with success in Berlin, Paris, and London. In company with her sister Therese, who was also a danseuse, she visited the U. S. in 1841. She retired from the stage with a large fortune in 1851. Her sister Therese was united in morganatic marriage with Prince Adalbert of Prussia in 1850, and was made Freifrau von Barnim by the king in the same year.

El'ster, Black, a river of Germany, rises in Saxony, flows north-westward, and enters the Elbe 8 miles E. of Wittenberg. Length, 105 miles.

Elster, White, a river of Germany, rises near the north-western frontier of Bohemia, flows northward, and after a course of 110 miles enters the Saale 3 miles S. of Halle (Prussia).

Elton', a shallow saline lake of Russia in the basin of the Caspian, government of Astrachan, about 49° 15′ N. lat., and 46° 30′ E. lon., 150 miles S. S. E. of the town of Saratof. It is 14 miles long, and has an area of 78 square miles. About 100,000 tons of salt are annually procured from it. In the summer it presents an appearance as if it were covered with snow.

El'ton (Romeo), D. D., LL.D., was born at Bristol, Conn., in 1790, and graduated at Brown University in 1813. He was ordained as a Baptist minister in 1817, and was (1825–43) professor of ancient languages in Brown University. He resided for a time in England (1845–69). He published sermons, biographical works, etc. Died Feb. 5, 1870, leaving $20,000 to Brown University, and the same amount to Columbian College, D. C.

Elutria'tion [from the Lat. *elu'trio, elutria'tum,* to "cleanse"], the process of preparing earths and pigments by washing them in large quantities of water, so that the heavier particles sink to the bottom, and the finer particles, remaining longer suspended, are gradually deposited. This operation is a very important one in preparing clay for the porcelain manufacture and some ores of iron and other metals for the furnace. The apparatus used for this purpose is a vat in which grinding wheels revolve, and into which a stream of water flows, but there are many special adaptations of the process.

El'vas [Sp. *Helves* or *Yelves*], a fortified frontier city of Portugal, in the province of Alemtejo, is about 125 miles E. of Lisbon and 12 miles W. of Badajos (Spain). It stands on a steep hill, is enclosed by walls, and is said to be the strongest fortress in Portugal. It contains many antique Moorish buildings, also a cathedral, several convents, a theatre, an arsenal, and a college. Elvas is supplied with water by a large Moorish aqueduct with several tiers of arches rising to the height of 250 feet. Its bishop is a suffragan of the archbishop of Evora. Pop. 11,088.

Elves. See Elf.

Elvira, a post-township of Johnson co., Ill. Pop. 1268.

El'wood, a township of Vermilion co., Ill. Pop. 1987.

Elwood, a post-village of Pipe Creek township, Madison co., Ind., on the Columbus Chicago and Indiana Central R. R. It is called also Quincy and Duck Creek. Pop. 310.

Ely, ee'le, an episcopal city or cathedral town of England, is in the country of Cambridge, and on the river Ouse, 72 miles N. N. E. of London and 16 miles N. N. E. of Cam-

bridge. It is situated in the fen country called the Isle of Ely. A monastery was founded here about 673 A. D. Here is a fine cathedral which is 535 feet long by 190 feet wide, and exhibits a combination of Early Norman and Gothic styles. It was commenced about 1080, and additions were made in the twelfth and fourteenth centuries. Ely became a bishop's see in 1107. It contains Trinity church, a handsome structure founded in 1321. Pop. in 1871, 8098.

Ely, Isle of, a level, fenny tract of England, in Cambridgeshire, is the southern part of the Bedford Level. It is bounded on the S. by the river Ouse. It was formerly in great part covered with water, but has been drained and reclaimed by numerous canals and ditches. Aquatic birds and marsh plants abound here. The soil is fertile, and produces good crops of hemp, flax, wheat, oats, etc.

Elyria, the capital of Lorain co., O., is beautifully situated at the confluence of the E. and W. branches of Black River, 25 miles W. of Cleveland and 7 miles S. of Lake Erie, at the junction of the Lake Shore and Michigan Southern and Lake Shore and Tuscarawas Valley R. Rs. It has a national bank, savings bank, three newspapers, a public library, telegraph college, seven churches, a gas-factory, and some of the finest business-houses in the State. It has valuable water-power. The manufacturing and sale of cheese, grindstones, building-stone, tobacco, confectionery, and screws are the chief businesses. The place has a rapid growth. Pop. in 1870, 3038; of Elyria township, including village, 4076. F. S. REEFY,
ED. "LORAIN CONSTITUTION" AND "ELYRIA VOLKSFREUND."

Elys'ian, a post-township of Le Sueur co., Minn. P. 852.

Elys'ium, or The Elys'ian Fields [Gr. ἠλύσιον πεδίον; Fr. *Élysée* or *Champs Élysées*], in classic mythology, the place to which the souls of the virtuous were supposed to be transported after death. Elysium was variously represented as a part of Hades or as an island in the Western Ocean. Some of the ancients imagined that the kingdom of Pluto was divided into two regions—Tartarus, in which the wicked were punished, and Elysium, the abode of the good.

Elysville (P. O. name, ALBERTON), a village of Howard co., Md., on the Baltimore and Ohio R. R. Pop. 302.

E'lyton, a post-village, capital of Jefferson co., Ala., on the Alabama and Chattanooga R. R., 54 miles N. E. of Tuscaloosa. It has one weekly newspaper. There are extensive iron-works in the vicinity.

El'ze (KARL FRIEDRICH), a German philologist, born in 1821, became professor at the gymnasium in Dessau. He wrote, among other works, "The English Language and Literature in Germany" (1864), "Sir Walter Scott" (1864), "Lord Byron" (1867), and published editions of English and American authors. He also edits (since 1868) the "Yearbook" of the German Shakspeare Society.

El'zevir, or Elzevier, the name of a family of Dutch printers who lived at Amsterdam, Leyden, and other places, and were celebrated for the accuracy and beauty of their typography. They published excellent editions of several classic authors between 1583 and 1681. The first eminent printer of the family was Lewis or Lodewijk, who was born about 1540. He lived at Leyden, and died about 1617, leaving four sons—Matthew, Lewis, Gilles (or Ægidius), and Bonaventure, who were all publishers. The business was continued by Abraham, a son of Matthew, and his partner Bonaventure, who published duodecimo editions of the classics which are still highly prized for their beauty and correctness. The Greek New Testament is among their masterpieces. A press was established in Amsterdam in 1638 by Lewis Elzevir (a grandson of Lewis first mentioned), who published good editions of numerous authors. Several other members of the family were distinguished printers.

Emana'tion [from the Lat. *e*, "out," and *ma'no, mana'tum*, to "flow"], in the religions of India, of ancient Persia, in Neo-Platonism, and in Gnosticism, a theory of ontology and of cosmogony which ascribes the origin of the universe and of all inferior beings to an outflow from the Deity. The name has also been applied to the good and evil influences which the heavenly bodies were formerly believed to send forth, and which were thought to determine the destinies of men.

Emancipa'tion [from the Lat. *eman'cipo, emancipa'tum*, to "liberate" (from *e*, "from," and *mancip'ium*, a "slave")], the act of freeing from subjection of any kind. In Roman law a son was regarded as the slave of his father, and could by a fiction of that law be freed by being sold (*mancipatus*) three times by the father. This enfranchisement was termed emancipation. Different modes of emancipation were afterwards recognized by Roman jurisprudence. In countries where that law prevails the word signifies the exemption of the son from the power of the father, either by express act or implication of law. By the civil law of France, majority (and emancipation) are attained at twenty-one, and a minor is emancipated by marriage. The word emancipation is used in a general sense to signify the liberation of a slave, or the admission of certain classes to the enjoyment of civil rights, as CATHOLIC EMANCIPATION (which see).

Emancipation, Proclamation of, the most important document ever issued by a President of the U. S., was issued by President Lincoln Sept. 22, 1862, as a notice to the Confederates to return to their allegiance, emancipation being proclaimed as a result which would follow their failure so to return. The real Proclamation of Emancipation was the supplementary document of Jan. 1, 1863. This act was simply a war-measure, based solely upon the President's authority as commander-in-chief of the army and navy.

PROCLAMATION OF EMANCIPATION.

I, Abraham Lincoln, President of the United States, and Commander-in-chief of the Army and Navy thereof, do hereby proclaim and declare that hereafter, as heretofore, the war will be prosecuted for the object of practically restoring the constitutional relation between the United States and the people thereof in those States in which that relation is, or may be, suspended or disturbed; that it is my purpose upon the next meeting of Congress to again recommend the adoption of a practical measure tendering pecuniary aid to the free acceptance or rejection of all the Slave States, so called, the people whereof may not then be in rebellion against the United States, and which States may then have voluntarily adopted, or thereafter may voluntarily adopt, the immediate or gradual abolishment of Slavery within their respective limits, and that the effort to colonize persons of African descent, with their consent, upon the continent or elsewhere, with the previously obtained consent of the government existing there, will be continued; that on the first day of January, in the year of our Lord one thousand eight hundred and sixty-three, all persons held as slaves within any State, or any designated part of a State, the people whereof shall then be in rebellion against the United States, SHALL BE THEN, THENCEFORWARD, AND FOR EVER FREE; and the military and naval authority thereof will recognize and maintain the freedom of such persons, and will do no act or acts to repress such persons, or any of them, in any efforts they may make for actual freedom; that the Executive will, on the first day of January aforesaid, by proclamation, designate the States and parts of States, if any, in which the people thereof respectively shall then be in rebellion against the United States; and the fact that any State, or the people thereof, shall on that day be in good faith represented in the Congress of the United States by members chosen thereto, at elections wherein a majority of the qualified voters of such State shall have participated, shall, in the absence of strong countervailing testimony, be deemed conclusive evidence that such State and the people thereof have not been in rebellion against the United States.

That attention is hereby called to an act of Congress entitled "An act to make an additional article of war," approved March 13, 1862, and which act is in the words and figures following:

"Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled, That hereafter the following shall be promulgated as an additional article of war for the government of the Army of the United States, and shall be observed and obeyed as such:

"ARTICLE —. All officers or persons of the military or naval service of the United States are prohibited from employing any of the forces under their respective commands for the purpose of returning fugitives from service or labor who may have escaped from any persons to whom such service or labor is claimed to be due; and any officer who shall be found guilty by a court-martial of violating this article, shall be dismissed from the service.

"SEC. 2. And be it further enacted, that this act shall take effect from and after its passage."

Also to the ninth and tenth sections of an act entitled "An act to suppress insurrection, to punish treason and rebellion, to seize and confiscate property of Rebels, and for other purposes," approved July 17, 1862, and which sections are in the words and figures following:

"SEC. 9. And be it further enacted, that all slaves of persons who shall hereafter be engaged in rebellion against the Government of the United States, or who shall in any way give aid or comfort thereto, escaping from such persons and taking refuge within the lines of the army; and all slaves captured from such persons or deserted by them, and coming under the control of the government of the United States, and all slaves of such persons found on (or being within) any place occupied by Rebel forces and afterwards

occupied by the forces of the United States, shall be deemed captives of war, and shall be for ever free of their servitude and not again held as slaves.

"SEC. 10. And be it further enacted, that no slave escaping into any State, Territory, or the District of Columbia, from any of the States, shall be delivered up, or in any way impeded or hindered of his liberty, except for crime or some offence against the laws, unless the person claiming said fugitive shall first make oath that the person to whom the labor or service of such fugitive is alleged to be due, is his lawful owner, and has not been in arms against the United States in the present rebellion, nor in any way given aid or comfort thereto; and no person engaged in the military or naval service of the United States shall, under any pretence whatever, assume to decide on the validity of the claim of any person to the service or labor of any other person, or surrender up any such person to the claimant, on pain of being dismissed from the service."

And I do hereby enjoin upon, and order all persons engaged in the military and naval service of the United States to observe, obey, and enforce within their respective spheres of service the act and sections above recited.

And the Executive will, in due time, recommend that all citizens of the United States who shall have remained loyal thereto throughout the rebellion, shall (upon the restoration of the constitutional relation between the United States and their respective States and people, if the relation shall have been suspended or disturbed) be compensated for all losses by acts of the United States, including the loss of slaves.

In witness whereof, I have hereunto set my hand and caused the seal of the United States to be affixed.

Done at the city of Washington, this twenty-second day of September, in the year of our Lord one thousand eight hundred and sixty-two, and of the Independence of the United States the eighty-seventh.

By the President: ABRAHAM LINCOLN.
WM. H. SEWARD, Secretary of State.

SUPPLEMENTARY PROCLAMATION.

Whereas, On the twenty-second day of September, in the year of our Lord one thousand eight hundred and sixty-two, a proclamation was issued by the President of the United States, containing among other things the following, to wit:

That on the first day of January, in the year of our Lord one thousand eight hundred and sixty-three, all persons held as slaves within any State, or any designated part of a State, the people whereof shall then be in rebellion against the United States, shall be thenceforward and for ever free, and the Executive Government of the United States, including the military and naval authority thereof, will recognize and maintain the freedom of such persons, and will do no act or acts to repress such persons, or any of them, in any efforts they may make for their actual freedom:

That the Executive will, on the first day of January aforesaid, by proclamation, designate the States and parts of States, if any, in which the people thereof respectively shall then be in rebellion against the United States, and the fact that any State, or the people thereof, shall on that day be in good faith represented in the Congress of the United States by members chosen thereto at elections wherein a majority of the qualified voters of such State shall have participated, shall, in the absence of strong countervailing testimony, be deemed conclusive evidence that such State and the people thereof are not then in rebellion against the United States:

Now, therefore, I, Abraham Lincoln, President of the United States, by virtue of the power in me vested as Commander-in-chief of the Army and Navy of the United States, in time of actual armed rebellion against the authority and Government of the United States, and as a fit and necessary war-measure for repressing said rebellion, do, on this first day of January, in the year of our Lord one thousand eight hundred and sixty-three, and in accordance with my purpose so to do, publicly proclaim for the full period of one hundred days from the day of the first above-mentioned order, and designate, as the States and parts of States wherein the people thereof respectively are this day in rebellion against the United States, the following, to wit: Arkansas, Texas, Louisiana, except the parishes of St. Bernard, Plaquemine, Jefferson, St. John, St. Charles, St. James, Ascension, Assumption, Terre Bonne, Lafourche, St. Mary, St. Martin, and Orleans, including the city of New Orleans, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia, except the forty-eight counties designated as West Virginia, and also the counties of Berkeley, Accomac, Northampton, Elizabeth City, York, Princess Ann, and Norfolk, including the cities of Norfolk and Portsmouth, and which excepted parts are, for the present, left precisely as if this proclamation were not issued.

And by virtue of the power and for the purpose aforesaid, I do order and declare that all persons held as slaves within said designated States and parts of States are, and henceforward shall be, free; and that the Executive Government of the United States, including the military and naval authorities thereof, will recognize and maintain the freedom of said persons.

And I hereby enjoin upon the people so declared to be free, to abstain from all violence, unless in necessary self-defence, and I recommend to them, that in all cases, when allowed, they labor faithfully for reasonable wages.

And I further declare and make known that such persons of suitable condition will be received into the armed service of the United States to garrison forts, positions, stations, and other places, and to man vessels of all sorts in said service.

And upon this, sincerely believed to be an act of justice, warranted by the Constitution, upon military necessity, I invoke the considerate judgment of mankind and the gracious favor of Almighty God.

In witness whereof, I have hereunto set my hand and caused the seal of the United States to be affixed.

Done at the city of Washington, this first day of January, in the year of our Lord one thousand eight hundred and sixty-three, and of the Independence of the United States of America the eighty-seventh.

[L. S.]

By the President: ABRAHAM LINCOLN.
WILLIAM H. SEWARD, Secretary of State.

Eman'uel, a county in the E. S. E. of Georgia. Area, 1000 square miles. It is bounded on the N. E. by the Ogeechee River and intersected by the Great Ohoopee. The surface is nearly level. Cattle, corn, rice, oats, tobacco, cotton and wool are raised. Capital, Swainsboro'. Pop. 6134

Emar'ginate [from the Lat. *emar'gino, emargina'tum*, to "take away the edge"], a botanical term applied to leaves which are notched or indented at the apex.

Em'aus, a post-village of Salisbury township, Lehigh co., Pa. Pop. 477.

Em'ba, or **Jem,** a river of Asia, in Toorkistan or the Kirgheez territory. It flows south-westward, and enters the Caspian Sea. Length, about 250 miles.

Embalm'ing [remotely from the Gr. *ἐν*, "in," and *βάλσαμον*, "balm," "resin," alluding to the ancient process], the preservation of dead bodies from decay by the application of antiseptic drugs or of suitable chemical reagents. This art early attained great perfection in Egypt. It appears to have arisen from belief in a future life and in the resurrection of the body. It was practised in various ways. In the most expensive method the brain and viscera were removed, their places being filled with bitumen and aromatic substances; the body was washed in the oil or tar of cedar, bound up in linen smeared with spices, asphalt, and various gums; and the whole was placed in a solution of natron (saltpetre or sodium nitrate) for seventy days. This process cost a silver talent, nearly $2000. The cheap methods dispensed with the evisceration, and yet many mummies (embalmed bodies) are found completely preserved by the inferior methods. It appears also that salt was freely used; and some authors believe that heat was also employed in the process. Embalming was also practised to some extent by the Jews, Assyrians, and ancient Persians, as also by the early Christians, who embalmed the bodies of some of the martyrs, probably by the simple application of aromatics. Throughout mediæval Europe rude embalming was practised upon the bodies of princes, and during the present century many improvements have been made in the process, which no longer aims at rendering bodies imperishable, but merely preserves them indefinitely. Various methods are now used. In some, arsenical liquids are injected into the blood-vessels. The chlorides of zinc, mercury, and aluminium, various other salts of aluminium, solutions of creasote from wood-tar, preparations of phenol or carbolic acid and of cresol or cresylic acid from coal-tar, etc., are successfully employed. Some of the very best methods are said to be secret.

Embank'ment, a mound of earth for a pier or quay, for defence against the sea or streams, or for carrying a roadway. In building embankments the slopes should be of a permanent nature, and the weight of the bank should not be so great as to force out the foot. The materials should be placed according to that angle at which they would begin to move if left to themselves. Gravel or hard stone may be laid at 34°, while clay is liable to slip if the materials are dressed to an angle of more than 26°. If required to resist the pressure of water on one side, the slope towards the water had better be 34°, and that towards the country 26°. The tendency of the subsoil of an embankment to be compressed under the load brought upon it

may be resisted by filling the core with light materials and by widening the base. The best way to counteract this tendency is to isolate the foundation by driving piles.

Care should be taken to free the seating of an embankment from any water that may filter through it. Covering the slopes with turf is a useful precaution, but this cannot be done when the bank is formed of gravel.

Among the greatest embankments of modern times are one of 1,750,000 yards on the Ulm and Augsburg Railway, and the Oberhäuser embankment of 2,500,000 yards cube on the Augsburg and Lindau line.

Embar'go [a Spanish word signifying "arrest," "impediment"], a restraint or prohibition imposed by the government of a country on merchant vessels or other vessels to prevent their leaving its ports. Embargoes are usually imposed in time of war, or when war is believed to be impending. They may sometimes prohibit the arrival as well as the departure of vessels. In Dec., 1807, the Congress of the U. S., at the request of President Jefferson, laid an embargo as an offset or retaliation against the British "Orders in Council." This embargo was repealed by Congress in Feb., 1809. (See INTERNATIONAL LAW No. II., by PRES. T. D. WOOLSEY, S. T. D., LL.D.)

Embarras, a township of Edgar co., Ill. Pop. 1280.

Embassador. See AMBASSADOR.

Em'bassy [for etymology see AMBASSADOR: Fr. *ambassade;* Ger. *Gesandschaft;* Lat. *legatio*], a diplomatic mission; the function of an ambassador. In a technical or limited application, embassy signifies a mission presided over by an ambassador: that is, a diplomatic agent of the highest rank. The term is sometimes applied to a company of persons sent on a mission, including one or more envoys, secretaries, etc.

Emb'den, a post-township of Somerset co., Me. P. 803.

Em'berton, a post-borough of Venango co., Pa. Pop. 488.

Em'ber Week [Lat. *qua'tuor tem'pora,* the "four seasons" (from this the English is probably a corruption); Fr. *quatre-temps;* Ger. *Quatember;* Dutch *temper*], a name given in the calendars of the Anglican and Roman Catholic churches (1) to the week after the first Sunday in Lent; (2) to the week after Whitsunday; (3) to that after the 14th of September; and (4) to that after the 13th of December. The Wednesday, Friday, and Saturday of these weeks are "ember days," fasts for imploring the Divine blessing on the fruits of the earth and upon the ordinations which are performed at these times. The fasts are said to have been instituted by Pope Calixtus I. in 229 A. D., but the times were fixed by Gregory VII., and confirmed by the Council of Placentia (1095).

Embez'zlement, in criminal law, is the act of fraudulently appropriating to one's own use property held under some fiduciary relation, such as that of clerk or servant. It is not to be confounded with larceny. The definition of this offence is rigid, so that this branch of the criminal law is entangled with perplexing distinctions. Larceny is defined to be "the felonious taking and carrying away the personal property of another." The word "taking," as here employed, has been closely interpreted by the courts, and generally considered not to include the case of property held in trust, particularly where it came into the possession of the trustee without first having passed into the possession of the real owner. There must have been a taking equivalent to a trespass. It became a maxim that without a trespass there could be no theft or larceny. So refined a distinction as the following has been maintained: Should a clerk or servant authorized to sell goods actually sell them, and, having received the price, convert the money to his own use, there is no larceny, because the master never had the *possession of the money,* and so the clerk could not be said to have "taken" it from him. On the other hand, if the clerk had put the money received on the sale into the master's money-drawer, and had afterwards fraudulently abstracted it, he would have committed larceny, for the act of depositing the money in the drawer would have placed it *constructively* in the master's possession. The moral quality of the two acts is substantially the same, yet by the common law the one is a crime, and the other is a simple breach of trust, for which the servant is responsible in a mere action for damages.

This imperfection in the law led, many years ago, to a statute in England, which created a new form of crime called "embezzlement." The early English statutes only included the case of misappropriation by clerks or servants of individuals or private corporations. This form of legislation was copied in this country. There is now in England a much more comprehensive scheme. (See 24 and 25 Vict., c. 96.) The present act not only includes the former cases, but embraces a great variety of cases of breach of trust, such as that by factors, brokers, agents, trustees of charitable societies, officers of cities, and public servants generally. The range of each enactment of this kind is very comprehensive, including not only positive wrongs, but all forms of wilful or fraudulent neglect of duty. It is by no means necessary under this legislation that the officer should appropriate the funds of a city to his own use. It is enough if he fraudulently appropriates or permits them to be appropriated to *any other use* than that to which they rightfully belong. The punishment is severe. The crime is made a felony, punishable by not more than fourteen nor less than three years of penal servitude, or else by imprisonment at hard labor for a fixed period. In the civil law embezzlement is recognized as a wrong, subjecting him who commits it to an action for damages or other proceeding by way of reparation. A salvor may forfeit his share of salvage compensation by "embezzlement;" the forfeited share accrues, not to the other members of his class, but to the owner of the property saved. T. W. DWIGHT.

Embla'zonry, pictures or figures on shields and coats-of-arms. Emblazoning is the art of adorning with ensigns armorial. (See BLAZONRY.)

Em'blem [Gr. ἔμβλημα (from ἐν, "in," and βάλλω, to "cast," to "put"), literally, "something inserted;" Lat. *emble'ma;* Fr. *emblème,* probably applied originally to a symbolical figure inserted in a shield or coat-of-arms], a figurative representation which by the power of association suggests to the mind some idea not expressed to the eye; a symbol; a type; thus, a balance is an emblem of justice. In bibliography, the term "book of emblems" is applied to a book containing a series of plates or pictures of emblematic subjects, with explanations, as the poems of Jacob Cats.

Em'blements [Norman Fr., probably from the Fr. *blé,* "grain," with the particle *en,* "in" or "on," prefixed], a term applied to the growing crops of cereal grains and vegetables raised by a tenant. By the law of England a tenant for life, whose estate depends on an uncertain event, or other tenant is entitled to the emblements, although his lease may terminate before harvest-time. If a tenant for life die, his personal representatives may after his death claim the products of his labor. But if a term be brought to a close by the voluntary act of the tenant, he is not entitled to the emblements.

Em'blica Officina'lis [the generic name is of Malay origin], a species of trees of the natural order Euphorbiaceæ, is a native of India and the Malay Archipelago. It produces a small round fruit, which is very acid, has medicinal properties, and is used to make pickles. The wood is hard and valuable. The bark is used for tanning and for dyeing cotton black.

Em'bolism [Gr. ἐμβολισμός, from ἐν, "in," and βάλλω, to "throw"], in the calendar, is an intercalation of a day, as the 29th of February in leap-year, or of a lunar month, as in the Greek and Hebrew calendars.

EMBOLISM, in pathology, is the presence of a clot (*em'bolus*) in the arteries or veins. Some writers also apply the name to the fixed venous clot (*thrombus*). Embolism in the brain is a recognized cause of apoplexy. An extensive embolism of the lungs may lead to sudden death; a smaller one may lead to local pneumonia, abscess, pyæmia, or gangrene. Embolism, though frequently fatal, is sometimes followed by recovery. The best treatment is the frequent administration of concentrated food and stimulants, keeping the patient in fresh air, and allaying irritation by opiates. Besides the above, some emboli appear to originate from a precipitation of pigmentary matter. Such cases are the result of disease.

Embolite, a chloro-bromide of silver, found in the silver ores of Mexico and Chili.

Embos'sing [from *boss,* a "protuberance"], in sculpture, carving, and architecture, is the forming in relief of any figure. The figures are said to be in high, middle, or low relief (*alto, mezzo,* or *basso rilievo*).

Embouchure [Fr., from *emboucher,* to "empty," literally, to "put into the mouth" or to "put the mouth to"], the mouth of a river; also that part of a wind musical instrument to which the lips of the performer are applied.

Embra'cery, in law, the offence of endeavoring to corrupt or bribe a jury or to influence a jury by any corrupt motive. To use indirect means to cause one's self to be chosen a juryman is also embracery. This offence is punishable by fine and imprisonment.

Embra'sure [etymology doubtful], in fortification, an opening made in the parapet of a fortified place or the breastwork of a battery through which the guns are pointed. The embrasures are usually made about two feet wide at the interior extremity or neck, and half as thick as the

parapet at the exterior crest. The sole or lower surface is at the height of about two and a half feet above the platform on which the carriage of the gun is placed.

Em'bro, a post-village of West Zorra township, Oxford co., Ontario, Canada, 10 miles from Woodstock, the county-town, has two weekly papers and about 600 inhabitants.

Embroi'dery [from the Fr. *broder*, to "embroider," probably from the Gaelic *brod*, a "goad," "something pointed"] is the art of working figures with a needle and thread on muslin and other fabrics. Embroidery on heavy materials is generally executed with silk, wool, or gold and silver thread, and is used for banners, church vestments, furniture covers, etc. Muslin embroidery is performed mostly with cotton, and employed for collars, caps, and various other articles of apparel. Embroidery with the common needle consists usually of a combination of ordinary stitches. A machine has recently been introduced into England and the Continent by which the most complicated patterns can be accurately executed by one person with 130 needles, all moving at once. One of these machines performs daily the work of fifteen hand-embroiderers. Several kinds of sewing-machines can be used for embroidering. The art of embroidery is of very ancient origin, and was brought to great perfection by the women of Greece and Sidon. It was extensively practised in mediæval times in Europe. The women of some barbarous races, like the North American Indians, often exhibit a marked degree of skill in embroidery.

Em'bryo [Gr. ἔμβρυος, "budding inwardly," from ἐν, "within," and βρύω, to "swell like a bud" before blooming], in animal anatomy and physiology, is the immature germ of the future organism; an account of the development of which is given in the article EMBRYOLOGY.

In botany, the embryo is the rudimentary plant found in the seed of phanerogamous plants. It consists of a radicle or undeveloped stem; of one, two, or more cotyledons or future seed-leaves; and the plumule, an incipient leaf or bud at the summit of the radicle. The dodders, and perhaps a few other dicotyledonous (or more strictly exogenous) plants, have no cotyledons, but only a spirally coiled, thread-like embryo inside the albumen, with sometimes a few plumule scales. (See GERM, by W. W. BAILEY, A. M.)

Embryol'ogy [from the Gr. ἔμβρυον, "something that grows or sprouts internally," and λόγος, a "discourse"], the history of the development of the young animal before birth. Embryology proper includes the description of all the changes, both anatomical and physiological, which take place in the body of the imperfect young, within either the uterus or the egg, in all classes of animals. The present article, however, will be devoted more especially to the embryology of the Vertebrata, or those animals having a bony skeleton, since the general plan of development is the same throughout this class, and is particularly important as illustrating the development of the embryo in the human species.

In all cases the development of the young animal begins from an *ovum*, or egg. The ova exist originally in the interior of the body of the female parent, where they are produced in certain organs contained in the cavity of the abdomen, termed *ovaries*. The ovaries, containing ova, are thus characteristic of the female organization, and form an essential part of its original structure. The ova, after being produced in the ovaries, at a certain period arrive at maturity, and are spontaneously discharged. If fecundated at this time by the influence of the male, they become developed into embryos; if not, they lose their vitality after a short period and perish. Thus the production of the embryo depends upon the concourse or combination of two sexual elements—namely, the ovum produced by the female, and the fecundating material or sperm produced by the male.

In some kinds of animals, such as birds, batrachians, and most of the reptiles and fishes, the egg is first discharged from the body of the female, and the development of the embryo takes place within it subsequently, the young animal being at last hatched from the egg externally; such animals are called *oviparous*, or egg-laying animals. In other instances, as in some fishes and reptiles, all the true quadrupeds, and the human species, the ova are retained within the body of the female while the development of the embryo is going on; so that at last the fully formed embryo is produced alive; such animals are called *viviparous*, because they produce living young, instead of laying eggs like the former. Nevertheless, the process is essentially the same in both cases, and differs only in the time during which the ovum is retained within the body of the female parent.

The ovum in its simplest form consists of a globular mass of albuminous matter mixed with oleaginous granules, and invested by a transparent, colorless, homogeneous membrane. The oleo-albuminous mass is termed the *vitellus*, or yolk; the investing layer is called the *vitelline membrane*. Of these two, the vitellus is the essential part of the ovum. It is that which yields the material for the first formation of the body of the embryo. The vitelline membrane is simply a covering intended to protect the vitellus, to maintain its shape, and to regulate for a short time the absorption of fluids. The vitellus, while still remaining in the ovary, contains a delicate, transparent vesicle, termed the "germinative vesicle," marked with a minute dot, called the "germinative spot." These names have been given to the bodies in question from the idea that they might have something to do with the commencement of growth or germination of the embryo, but it is doubtful whether they have any such significance; and it is generally believed that they are rather connected with the growth and maturity of the ovum itself before impregnation has occurred.

In the human species and in the quadrupeds generally the ovum, as above described, forms a little sphere about $\frac{1}{120}$ of an inch in diameter. It is therefore nearly invisible to the naked eye, and requires examination by the microscope in order to distinguish its characters.

FIG. 1.

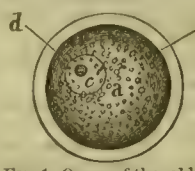

FIG. 1. Ovum of the rabbit, from the ovary, magnified 90 diameters: *a*, vitellus; *b*, vitelline membrane; *c*, germinative vesicle; *d*, germinative spot.

In the quadrupeds this minute form and simple structure are amply sufficient, since the impregnated ovum is retained within the body of the female during the development of the embryo, and abundantly supplied with nourishment from the parent organism. But in the oviparous classes, where the development of the embryo takes place outside the body of the parent, the egg is larger in size and more complicated in structure, and contains a store of nutritious material, as well as certain additional protective envelopes. In the common fowl, for example, the vitellus or yolk, which is the only part of the egg produced in the ovary, is nearly an inch in diameter, and contains a great abundance of oleaginous as well as albuminous material. After its discharge from the ovary, and during its downward passage through the generative canal, the size of the egg is still further increased by the deposit around the yolk of a layer of pure albumen, secreted by the lining membrane of the canal, and forming the so-called "white of egg." In the lower portion of the generative passage there are added to the outside of the albumen two fibrous membranes, called the "shell-membranes;" and lastly, the calcareous shell, formed of a consolidated layer of the salts of lime. These fibrous and calcareous envelopes serve to protect the embryo, while the albumen and the yolk supply it with the requisite nourishment during its formation in the egg.

FIG. 2.

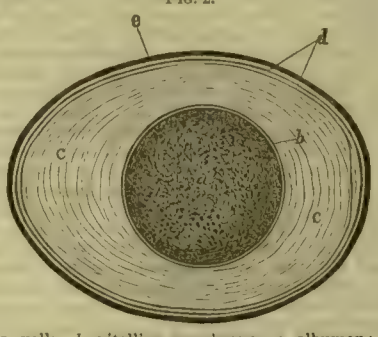

FIG. 2. *a*, yolk; *b*, vitelline membrane; *c*, albumen; *d*, shell-membranes; *e*, egg-shell.

In all instances, without exception, the first indication of the commencing formation of the embryo in the ovum is what is called the spontaneous division or *segmentation* of the vitellus. This process consists in the separation of the globular vitellus into two smaller globules or hemispheres by the appearance of a furrow running round the vitellus like an equator, which gradually deepens until it has completely separated the two hemispheres from each other. At the same time, or a little later, a second furrow, placed at right angles to the first, runs round the vitellus in another direction; and thus the two secondary globules are divided into four. By a repetition of this process the vitellus, which had originally the form of a simple sphere, becomes converted into a mulberry-shaped mass of minute globules, called the "vitelline spheres." These globules become condensed into the form of organized cells; and from these cells, in the simplest cases, the body of the embryo is directly formed, without the production of any accessory organs.

In the vertebrate animals the vitelline spheres, resulting from the segmentation of the vitellus, when converted into organized cells, form a cellular layer or continuous membrane upon the surface of the impregnated ovum. This membrane, formed exclusively of similar flattened cells, adherent to each other by their edges, is called the *blasto-*

FIG. 3.

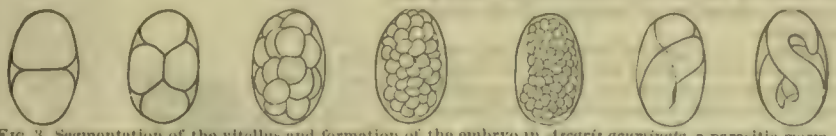

FIG. 3. Segmentation of the vitellus and formation of the embryo in *Ascaris acuminata*, a parasitic worm.

dermic membrane. It is the first appearance of a truly organized structure in the interior of the impregnated ovum, and forms the basis for the formation of the body of the embryo. In some instances, in the lower orders of the vertebrate class, where the impregnated eggs are laid in the water, and where an abundance of warmth, oxygen, and nutritious fluid is supplied by the surrounding medium—as, for example, in the frog—the subsequent process is very simple, or at least is not complicated with the formation of any accessory organs. In these cases the whole of the vitellus, and consequently the whole of the blastodermic membrane, is directly converted into the body of the embryo. The plan upon which this development takes place is as follows:

An elongated oval spot appears upon a certain part of the blastodermic membrane, where the tissue of the membrane is thicker, denser, and more opaque than elsewhere. This spot, which is the first sketch of the actual form of the future embryo, is called the *embryonic spot*. Its anterior extremity will subsequently become the head, and its posterior extremity the tail. As the cells of the embryonic spot become more numerous, smaller, and more closely amalgamated, its appearance changes towards its central portions, where, instead of being opaque, it becomes homogeneous and pellucid in appearance. The central area or space in which this change occurs is called the *area pellucida;* and finally there appears, in the middle of this transparent space, a longitudinal line or trace, indicating the position of the future spinal column, and known by the designation of the *primitive trace*.

FIG. 4.

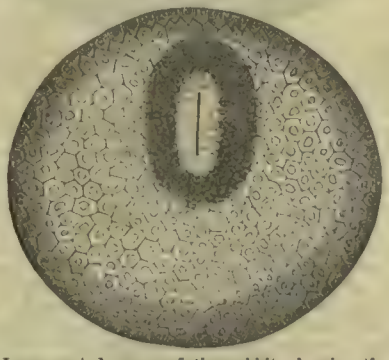

FIG. 4. Impregnated ovum of the rabbit, showing the blastodermic membrane formed of cells, the embryonic spot, the area pellucida, and the primitive trace.

In this way is determined the location of the fundamental part of the structure of the vertebrate animal, for the spinal column is the most important portion of the whole skeleton, and the formation of all the remaining parts of the body takes place with reference to it.

In every vertebrate animal the subsequent development of the body goes on simultaneously in two different directions—namely, from before backward, and from behind forward. From the edges of the primitive trace, on the right and left sides, the substance of the blastodermic membrane becomes thickened and elevated into two longitudinal and parallel ridges, which of course include between them a longitudinal furrow. These ridges are called the *dorsal plates*. As they increase in growth their upper edges approach each other, and the furrow between them becomes deeper and more like a canal. In this canal, which is still open along the back, are formed the spinal cord and the brain. But the dorsal plates, constantly approaching each other, at last meet, and unite by their edges along the median line of the back; thus converting the furrow which existed between them into a closed cavity, in which are now contained the brain and spinal cord. Thus, the dorsal plates, by their union with each other along the median line, complete the formation of the external parts of the body in a posterior direction, and the brain and spinal cord are enclosed in an elongated cavity situated behind the column of the bodies of the vertebræ.

At the same time a similar condensation and growth extends from the edges of the primitive trace in a direction outward and forward. These growing portions are called the *abdominal plates* of the blastodermic membrane; and they continue to extend forward until they embrace the abdominal cavity in front, just as the dorsal plates embraced the spinal canal behind. At last they also unite with each other by their edges, and the external parts of the body are then cicatrized and consolidated upon the median line, both anteriorly and posteriorly. The alimentary canal and its accessory organs are thus enclosed by the abdominal plates in an abdominal cavity, situated in front of the column of the bodies of the vertebræ.

As thus far described, the process of development relates to the growth of the external portions of the body, and that part of the nervous system which corresponds with them—namely, the brain and spinal cord, and the nerves derived therefrom. The dorsal and abdominal plates, as they grow thicker and more condensed, begin to show in their substance the distinction of the various tissues. The external integument, the tissue of the voluntary muscles, the cartilages and bones, the organs of special sense, the nerves of sensation and voluntary motion, and the white and gray matter of the brain and spinal cord, are thus formed in the substance of the growing material. All the organs and tissues just enumerated, notwithstanding their different functions, are closely related to each other in one respect; that is, they are destined to bring the animal body into relation with the external world by means of sensation, consciousness, volition, voluntary movement, and the mechanical reception and expulsion of nutritious or effete materials. They are accordingly known as the "organs of animal life;" and they are all formed from the original cells of the *external layer* of the blastodermic membrane.

There is also, however, an *internal layer* of the blastodermic membrane; and from this layer are formed the alimentary canal and its glandular appendages, or the organs in which digestion, absorption, and secretion are to be carried on, and in which the muscular actions are involuntary and unconscious. They may, therefore, be regarded as the "organs of vegetative life." The alimentary canal is at first an oval sac, enclosed on all sides by the external abdominal walls. But subsequently two openings are formed, one at its anterior and one at its posterior extremity—namely, the mouth and the anus; and the original sac is thus converted into a true canal, open at both ends. At the same time the alimentary canal grows very rapidly in the direction of its length, thus becoming converted into a comparatively long, narrow, and convoluted tube, and afterwards showing the distinctions between the œsophagus, the stomach, and the different parts of the small and large intestine.

These are the general features of the development of the embryo in all vertebrated animals. There are other details which relate to the special growth of particular parts, and to the so-called metamorphoses or transformations which take place in particular species, and which are nothing more than the successive appearance and disappearance of particular organs, which are adapted to the life of the animal at different stages of growth. Thus, in the young tadpole, when first hatched from the egg, the mouth is a round orifice provided with a suctorial apparatus and adapted for feeding on vegetable matters; respiration is entirely aquatic, and is performed by means of gills; there are no limbs, but voluntary movement is accomplished by a large and muscular tail, the animal living altogether under the surface of the water. Afterwards the mouth enlarges into a wide transverse opening, adapted for the seizure of living prey; the gills disappear and lungs are developed, while the mode of respiration changes from aquatic to aërial; and finally, anterior and posterior legs grow from the corresponding parts of the body, becoming powerful organs for both swimming and leaping, while the tail ceases to grow, becomes atrophied, and disappears. Thus, the tadpole grad-

ually acquires the organs and the appearance of a perfect frog. This change, in the case of the tadpole, is called a "transformation," because it happens after the young animal has escaped from the egg; but equally important changes take place in the embryo of the higher animals while they are still retained within the egg or in the uterus of the female parent.

Besides the essential and general features of embryonic development detailed above, there are, in all the higher classes, certain secondary or accessory organs developed during embryonic life, which will require a further description.

The first of these is known as the *umbilical vesicle*. In the process of development, as already described, the abdominal walls, growing together upon the median line, enclose directly the whole of the vitelline cavity, which subsequently, of course, becomes the cavity of the intestine. But in many of the fishes and reptiles, and in all birds and quadrupeds, the abdominal walls approach each other before they have embraced the whole of the vitellus, so that the vitelline cavity is thus separated, by a kind of constriction, into two parts. The internal part, which is fully embraced by the abdominal walls, is, as before mentioned, the cavity of the intestine; but the external part, which is left by this constriction outside the abdomen, is the umbilical vesicle. This name is given to it because it is really a vesicle, containing some of the remains of the vitellus, and because it still communicates with the cavity of the intestine through the umbilicus or navel. This communication is at first short and wide; but as development proceeds, the umbilical vesicle gradually retreats farther from the abdomen, while the passage of communication becomes converted into a comparatively long and narrow canal. In many of the quadrupeds and in the human species the walls of this canal even coalesce with each other at an early period, so that the umbilical vesicle then forms a separate cavity or sac, connected with the abdomen only by a slender solid pedicle. One or two minute blood-vessels run out along this pedicle, and ramify upon the surface of the umbilical vesicle. The umbilical vesicle is undoubtedly at first a reservoir of nutritious material, and remains so throughout embryonic life in all those species where the vitellus was originally of large size; but in the quadrupeds it very early loses its importance, and is superseded by other sources of nourishment. In the human subject it is difficult to distinguish it after the third month of embryonic existence.

The next accessory organ of the embryo is the *amnion*. This is a delicate and transparent membrane, which turns up from the edges of the abdominal walls over the back of the embryo, and thus envelops it in a secondary cavity. This is called the "cavity of the amnion;" the albuminous liquid which it contains, and in which the embryo is bathed, is called the "amniotic fluid." The amnion is accordingly an extension of the outer layer of the blastodermic membrane, and is continuous with the integument of the embryo. In other words, the external layer of the blastodermic membrane in these cases is developed into two different parts. That which immediately invests the body of the embryo is its integument, and part of its permanent structure; that which turns backward at the edges of the abdominal opening is the amnion, and an organ of embryonic life. The amnion at first closely embraces the body of the embryo, but afterwards it expands more rapidly, and the amniotic fluid increases in quantity, so that the young animal may move freely within its cavity when the muscular system begins to exhibit signs of activity.

The third and last accessory embryonic organ is the *allantois*. It is so called from the Greek ἀλλᾶς, ἀλλᾶντος, a "sausage," because in many cases it is a sac or bag of an elongated cylindrical form. In all instances it is an outgrowth from the lower part of the intestine. It shows itself at first as a small bud or diverticulum, shaped somewhat like the finger of a glove, which protrudes from the abdominal opening in front, and then rapidly expands in every direction until it has entirely enveloped the embryo, as well as the amnion, in a second exterior covering. Its walls are exceedingly vascular, their vessels being derived from those of the intestine, of which the allantois itself is an offshoot. Thus, when the allantois has become completely formed, the external surface of the embryonic mass is a continuous vascular membrane, in which the blood-vessels of the embryo ramify in great abundance.

This anatomical feature will serve to indicate the usefulness and the function of the allantois. It is the organ of nourishment and respiration for the embryo. In the fowl's egg, the allantois, which is placed immediately underneath the calcareous shell and shell-membranes, is very active during the latter half of the period of incubation. It absorbs oxygen from the external air through the porous egg-shell, and exhales carbonic acid, thus serving to renovate and arterialize the blood, as the lungs will do in the young chick after being hatched. In the viviparous animals, as the quadrupeds, the action of the allantois is still more important. The ovum in these animals being of minute size, without any abundant store of nutritious material, and being retained, after fecundation, within the body of the female parent, the young embryo is entirely dependent upon the maternal system both for respiration and nourishment. The vascular allantois here, enveloping the embryo, comes in contact with the vascular lining membrane of the uterus, and thus the blood-vessels of the embryo constantly absorb from the blood-vessels of the mother the substances requisite for its nourishment and growth. In many kinds of animals the allantois even contracts a more or less intimate adhesion with the lining membrane of the uterus at particular spots, where the process of absorption and transudation is carried on with greater rapidity.

Fig. 5.

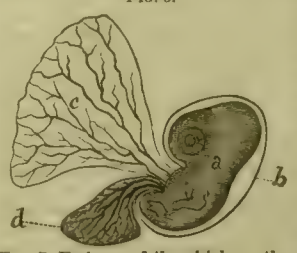

Fig. 5. Embryo of the chick on the seventh day of incubation: *a*, body of the embryo; *b*, amnion; *c*, a portion of the umbilical vesicle; *d*, commencing growth of the allantois.

Fig. 6.

Fig. 6. Egg of fowl on the twelfth day of incubation. The shell and shell-membranes have been removed, showing the vascular allantois, which has grown so as to envelop all the remaining portions of the egg.

In the human species the allantois commences its growth in the same manner as in the inferior animals, but exhibits certain modifications in its subsequent development which have caused it to be known by another name. It does not present the form of an elongated cylindrical sac, but is, on the contrary, irregularly globular in form, corresponding to the shape of the cavity of the uterus in which the embryo is developed. It forms, however, a complete envelope or external tunic for the embryo, consisting of a continuous vascular membrane of more or less fibrous consistency and texture. It has accordingly received the name of the *chorion*. The human embryo, therefore, is enveloped in two distinct membranes—namely, the chorion externally and the amnion internally. Both these membranes are vascular, but the blood-vessels of the amnion are derived from the integument of the embryo, those of the chorion from the intestinal canal.

Another important modification of the human chorion is that at an early period it becomes shaggy or velvety by the growth of a multitude of minute filamentous projections or "villosities" upon its outer surface. These villosities become branched and divided, forming so many tufted filaments, by which the power and activity of absorption by the chorion is greatly augmented. Soon after the first month, however, these villosities cease their growth over about three-quarters of the surface of the chorion, which thus becomes smooth and bald, while over the remaining quarter they grow more rapidly than before, become excessively developed both in numbers and in ramification and vascularity, so that the chorion here becomes converted into a thickened and spongy mass of villosities, which are penetrated everywhere with an abundance of looped and ramifying blood-vessels. When this portion of the chorion is fully developed, it forms a distinct organ, which is known by the name of the *placenta*. The placenta, accordingly, in the human species, is the especial organ of nourishment for the embryo. It has become well developed, and easily

distinguishable from the remaining portions of the chorion, by the end of the third month of embryonic life.

The amnion and the chorion, therefore, although they are termed the "membranes" and the "appendages," are in reality a part of the body of the embryo—as much so as any other of its external or internal organs. The placenta, however, includes also a portion of the tissues of the mother; for at the same time that the chorion is becoming excessively shaggy and vascular at the spot which is afterwards to be the placenta, the lining membrane of the uterus also assumes, at the corresponding point, a similar increased development. In both cases it is the blood-vessels which preponderate over the remaining tissues, becoming adherent to each other, and mutually interpenetrating through the entire thickness of the organ. Thus, the placenta, when fully formed, is a double organ, containing both embryonic and maternal vessels, and presenting an extensive vascular surface for reciprocal absorption and exudation. There is at no time any actual communication between the cavities of the two sets of vessels, but the nutritious materials transude through the thin vascular walls, and in this way supply to the embryo everything essential to its growth.

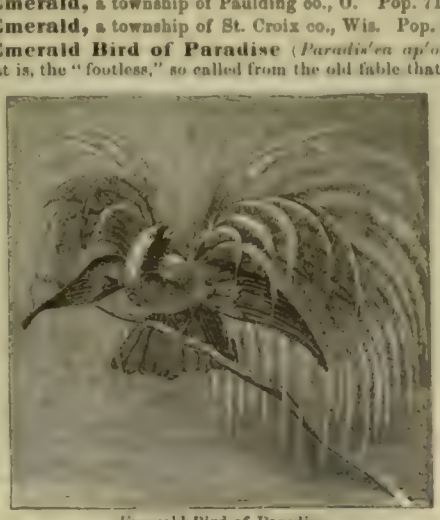
When the development of the embryo is complete the muscular walls of the uterus contract, the membranes are ruptured, the placenta is separated from its attachments, and the whole expelled from the uterine cavity. The placenta is then no longer available as an organ of nourishment, and is cast off as a useless appendage. But in the mean time the lungs and the alimentary canal have been gradually becoming developed by internal growth, and are now capable of performing their natural functions. After birth, accordingly, the act of respiration and the absorption of nourishment are accomplished in the young infant independently by the aid of internal organs, while during embryonic life they were performed by the placenta, supplied in great part for this purpose by the blood of the mother.

J. C. Dalton.

Em'bury (Emma Catherine), an American writer whose maiden name was Manley, was born in New York in 1806, and was married in 1828 to Daniel Embury, Esq., of Brooklyn. Among her works are "Guido and other Poems," "Constance Latimer, or the Blind Girl," and "Nature's Gems, or American Wild Flowers." Died Feb. 10, 1863.

Embury (Philip), recognized as the "founder of American Methodism," was born at Ballygarane, Ireland, in 1728. He became a member and "local preacher" of Wesley's society at Court-Mattress, Ireland. In 1760 he emigrated to New York. He began to preach there in 1766 in his own house, mostly to his own countrymen. Later he preached in an old rigging-loft, and at last succeeded in erecting "Old John street church." Embury, being a carpenter, worked on it himself. He built with his own hands its pulpit, and on the 30th of Oct., 1768, preached from it the dedicatory sermon of the humble structure—the first Methodist chapel of the New World. Embury afterwards settled in Salem, N. Y., where also he founded his denomination, and where it grew into the prosperous Troy conference, and where he died in 1775. His church commemorates these by a monument.

Em'den, or **Emb'den,** a fortified seaport-town of Prussia, in the former kingdom of Hanover, is on the N. shore of the Dollart, near the mouth of the Ems, about 70 miles W. N. W. of Bremen; lat. 53° 22′ N., lon. 7° 12′ 38″ E. It is intersected by several canals, which are crossed by about thirty bridges. It is well built, and contains a handsome town-hall, an exchange, a custom-house, a gymnasium, a school of navigation, and a deaf and dumb asylum. Here are manufactures of linen fabrics, hosiery, hats, sailcloth, starch, soap, etc. The port of Emden has shallow harbors, outer and inner, but the roadstead is deep enough for large ships. Pop. in 1871, 12,588.



Em'erald [Gr. σμάραγδος; Fr. *émeraude;* Sp. *esmeralda;* Ger. *Sma'ragd*], a beautiful green precious stone, a variety of beryl, a silicate of alumina and glucina. It occurs in six-sided prisms, which are highly prized as ornamental gems. Its color, which is perhaps the most beautiful of all the varieties of green, is ascribed to the oxide of chromium that it contains. It is stated that a perfect specimen of this gem has been sold for $5000. Its value depends chiefly on its color. The largest emeralds occur in Siberia on the river Tokowoia; one in the Royal collection weighs sixteen and three-fourths pounds Troy, another six pounds. The finest modern emeralds are found in South America, especially at Muzo in Colombia. Emeralds of inferior quality are procured at Canjargum in Hindostan, and in the Henbach Valley near Salzburg. F. Cailliaud rediscovered (about 1818), in Mount Zabarah in Upper Egypt, the emerald-mines from which the ancients obtained many emeralds. A rare green variety of sapphire is sometimes called Oriental emerald. Emerald copper is a synonym of dioptase; emerald nickel for zaratite, a compound of carbonate and hydrate of nickel, found at the chrome-mines of Texas, Pa.

Emerald, a township of Faribault co., Minn. Pop. 748.

Emerald, a township of Paulding co., O. Pop. 717.

Emerald, a township of St. Croix co., Wis. Pop. 206.

Emerald Bird of Paradise (*Paradis'ea ap'oda*), [that is, the "footless," so called from the old fable that the

Emerald Bird of Paradise.

bird of paradise has no feet, but always flies without resting], the best known and most elegant of the birds of paradise, is a native of New Guinea (Papua), where it is killed in great numbers for its beautiful plumage, which brings a high price in the market.

The skins with the plumage are used in the East for ornamenting turbans, and in Europe and America for adorning ladies' head-dresses. About 1500 or 2000 are annually imported into Europe, chiefly by way of Batavia. The back part of the neck is of a pale gold color, the throat and fore part of the richest changeable golden green, the breast a deep purple, the body and tail a fine chestnut. The body feathers are frequently dyed to improve the natural tint. The female is said to furnish the most highly prized feathers, though during life, at least, it appears that the male is by far the more splendid bird, being provided with conspicuous floating plumes of astonishing beauty.

Emer'sion [Lat. *emer'sio,* from *emer'go, emer'sum,* to "emerge or rise into view"], in astronomy, is the reappearance of the sun, moon, planet, or star from behind the celestial body by which it was hidden in an eclipse or occultation. The phenomena of immersion and emersion are useful in determining the longitude of places.

Em'erson, a township of Gratiot co., Mich. Pop. 590.

Emerson (George Barrell), LL.D., an American teacher and writer, born in Kennebunk, Me., Sept. 12, 1797. He lived in Boston for many years, and was president of the Boston Society of Natural History. He was the first head-master (1821–23) of the Boston English High School for boys. Among his works are "Lectures on Education" and a "Report on the Trees and Shrubs growing naturally in the Forests of Massachusetts" (1846).

Emerson (Rev. John S.), missionary, was born at Chester, N. H., in 1801, graduated at Dartmouth in 1826, and at Andover in 1830. He went to the Sandwich Islands, and aided in preparing an "English Hawaian Dictionary." Died Mar. 28, 1867.

Emerson (Ralph Waldo), LL.D., an American poet and essayist. Lord Clarendon said of Lord Falkland, secretary of state to Charles I., that, as his house was within ten miles of Oxford, "the most polite and accurate men of that university frequently resorted and dwelt with him, as in a college situated in purer air; so that his house was a university in less volume, whither they came not so much for repose as study."

There seems still to be some benignant Fate which provides suitably for the suburbs of university towns. Within ten miles of Harvard College there has been for many years one modest roof which has afforded to "the most polite and accurate men" of that university some such "college in purer air;" for it has been the residence of Ralph Waldo Emerson.

Mr. Emerson was born in Boston, Mass., May 25, 1803, and was the son of Rev. William Emerson and Ruth (Haskins) Emerson. He had a minister for an ancestor in every generation for eight generations back, either on the paternal or maternal side. He was fitted for college at the public schools of Boston, and graduated at Harvard College in

1821. He was not among the very highest scholars of his class, but in his junior year won a "Bowdoin prize" for a dissertation on the "Character of Socrates," and another in his senior year for an essay on "The Present State of Ethical Philosophy." He also won a "Boylston prize" for declamation, and he was "class poet." For five years after leaving college he taught school, chiefly in Boston, where he assisted his elder brother, William, in conducting a successful school for girls. In 1826 he was "approbated to preach," though his name does not appear among the graduates of the Harvard Theological School. In March, 1829, he was ordained as colleague to Rev. Henry Ware of the Second Unitarian church in Boston. In 1832 he resigned his pastoral charge, having announced in a sermon his unwillingness longer to administer the rite of the Lord's Supper. This sermon was never published, but copies of it exist in manuscript. In Dec., 1832, he sailed for Europe, remaining absent nearly a year. Soon after returning he began his career as a lecturer before the Boston Mechanics' Institute, his subject being "Water." He gave also three other lectures—two on "Italy," and one on the "Relation of Man to the Globe." In 1834 he gave in Boston a series of biographical lectures on Michael Angelo, Milton, Luther, George Fox, and Edmund Burke; the first two of which were published in the "North American Review." Since that time he has given many courses of lectures in Boston, and has been one of the best-known lecturers throughout the United States. Perhaps no other man has rendered such continued service in this field. It is said that he lectured for forty successive seasons before the Salem (Mass.) Lyceum. He has also made repeated lecturing tours in the Western States, and has even lectured in California and in England.

In 1835, Mr. Emerson took up his residence in Concord, Mass., and published in the following year a thin volume called "Nature." It marked a new era in American thought—was received with sharp criticism from many quarters, and with corresponding enthusiasm by a small circle of admirers. It took twelve years to sell five hundred copies. This was followed by several orations before literary societies on such themes as "The Method of Nature," "Man Thinking," and "Literary Ethics." More important even than these was his remarkable "Address before the Senior Class at Divinity College, Cambridge," delivered July 15, 1838. From these various addresses and publications may be dated the intellectual movement then vaguely stigmatized as "Transcendentalism." This was a reaction against formalism and tradition, and brought together a variety of minds, some profoundly mystical, others full of projects for action. It led to some excesses and affectations, but was on the whole a valuable impulse towards many good things. The four volumes of "The Dial" contain a lasting memorial of that important seed-time of thought.

Mr. Emerson's two volumes of "Essays" were collected and published in 1841 and 1844, and his "Poems" in 1846. His miscellaneous addresses remained uncollected till 1849, in America, though they had been reprinted collectively in England in 1844. Visiting the mother-country in 1847, Mr. Emerson found awaiting him a large circle of admirers, whose allegiance he has always retained. In 1850 he published "Representative Men," given previously as a course of lectures in Boston. In 1852 he took part in preparing the memoirs of Margaret Fuller Ossoli. His "English Traits" appeared in 1856, "The Conduct of Life" in 1860, and "May-Day and other Poems" and "Society and Solitude" in 1869.

Though Mr. Emerson is often assigned to the class of metaphysicians or "philosophers," yet the actual traits of his intellect clearly rank him rather among poets or literary men. All his methods are literary rather than scientific, although he has won some of his warmest admirers among scientific men, as in the case of Professor Tyndall. His statements are sometimes subtle, sometimes profound, sometimes noble and heroic, but scarcely ever systematic. He rests in his intuitions, rarely attempts even the rudiments of method, but constantly recognizes, in his own words, "the opposite negations between which, as with cords, our being is swung." But it is claimed by his admirers that (quoting his words again) "We are too young by some ages yet to form a creed," and that, while not aiming at the kind of work done by Herbert Spencer, for instance, Emerson often gives in some single phrase an illumination that seems to extinguish Herbert Spencer's lights, as a sunbeam makes gas-lamps superfluous.

In viewing Mr. Emerson simply as a literary artist, the reader must still complain of this tantalizing fragmentariness, this disregard of all the unities, this structural defect. Even in his poems his genius is like an æolian harp, that now gives, now wilfully withholds, its music; while some of his essays seem merely accidental collections of loose leaves from a note-book. Yet as one makes this criticism, one is shamed into silence by remembering many a passage of prose and verse so majestic in thought and rhythm, of quality so rare and utterance so delicious, as to form a permanent addition to the highest literature of the human race.

Mr. Emerson wrote in 1844 that all our books were European, that we were "sent to a feudal school to learn democracy;" and demanded that Americans should "advance out of all hearing of others' censures, out of all regrets of their own, into a new and more excellent social state." More than any previous literary man among us, he set the example of ignoring European traditions, methods, and literary properties wherever these could be better superseded by our own. He drew his habitual illustrations from American society and manners, and was more ready to write of the pine woods and the humble-bee than of the nightingale and asphodel. It seems hardly credible that this should have been ridiculed by the critics as "a foolish affectation of the familiar;" but the fact of the ridicule shows the need of the innovation. If that state of things has now passed by, and if our literature is no longer provincial, it is to Mr. Emerson that we are most indebted.

It is well known that his position on religious questions has been that of a philosophical radical, and that he has been quite detached from the church organizations of the time. He took this position, once for all, in a sentence which attracted much attention in his "Divinity Hall Address:" "The assumption that the age of inspiration is past, that the Bible is closed, the fear of degrading the character of Jesus by representing him as a man, indicate with sufficient clearness the falsehood of our theology." His precise attitude as to the conception of a Deity and the belief in personal immortality might be harder to define. He declares eloquently, however, in one of his orations, that "there is a sublime and friendly Destiny by which the human race is guided—the race never dying, the individual never spared—to results affecting masses and ages."

Though Mr. Emerson is, like Goethe, a prophet of Self-Culture, he has never held himself aloof, like Goethe, from the immediate public agitations of his time, but has always practically recognized the truth of his own formula, "To-day is a king in disguise." He has always lent his voice in behalf of any momentous public interest. He was always frankly identified with the anti-slavery movement, and, though averse to extemporaneous speech, and ill at ease in that form of service, he often took part in the meetings of the abolitionists. In 1844 he gave an elaborate and remarkable address on the anniversary of emancipation in the British West Indies. He signed, with his wife, the call for the first "National Woman's Rights Convention" in 1850. He is a vice-president of the Free Religious Association, and has several times addressed its conventions. He is also an overseer of Harvard University, and received from that institution the degree of doctor of laws in 1866. He is a member of the American Academy of Arts and Sciences, of the American Philosophical Society, and of the Massachusetts Historical Society.

Mr. Emerson has been twice married—once, in 1830, to Ellen Louisa Tucker of Boston, who died the following year; and again, in 1835, to Lidian Jackson of Plymouth. He has three children, two daughters and one son. The son, Edward Waldo, graduated at Harvard College in 1866, and has since pursued the study of medicine. Of the daughters, the elder, Ellen, is unmarried; the younger, Edith, is the wife of William H. Forbes, Esq., of Milton, Mass., and has several children. Mr. Emerson has just returned with his elder daughter from Europe, reaching home May 27, 1873. On his arrival at the Concord station he found all the children of the public schools drawn up to receive him, accompanied by many citizens and by a band of music. They all escorted him in a procession to his house, which had been destroyed by fire just before his departure from home, and was rebuilt in his absence. A triumphal arch, decorated with flowers and bearing the word "Welcome," had been placed before it. Beneath this, and between two lines of children, Mr. Emerson and his daughter entered their home. It was a spontaneous tribute to the love and reverence won for this eminent author in his own village by his gracious manners and his simple and noble life.

T. W. Higginson.

Emerson (Rev. William), the father of Ralph Waldo Emerson, was born at Concord, Mass., May 6, 1769. His grandfather, Rev. Joseph Emerson, was minister of Malden, and his father, Rev. William Emerson, died a chaplain in the Revolutionary army in 1776. The younger William Emerson graduated at Harvard College in 1789. He was the first minister of Harvard, Mass., and afterwards (1799–1811) pastor of the First church (Unitarian) of Boston, Mass. He published various discourses, a "Selection of Psalms and Hymns" (1808), and wrote a "History of the First Church of Boston," which was published in 1812. He was an accomplished writer, and one of the best orators of his day. Died May 12, 1811.

Emery, one of the hardest minerals known, ranking next to the diamond in its power of cutting or abrading hard substances. It is a variety of the species corundum or sapphire, of a dark reddish brown, black, or gray color, and consists of nearly pure alumina and oxide of iron. It is found in large masses, and much resembles fine-grained iron ore, for which it has often been mistaken. It is obtained chiefly from Asia Minor and the island of Naxos in the Grecian Archipelago. At Naxos 60,000 quintals are sold annually at from twelve to fourteen drachmæ (about thirteen francs) the quintal. Nearly half of the quantity is exported to England, generally as ballast in homeward-bound vessels, where it is used chiefly in grinding glass. It has also been found at Chester, Mass., in a vein with magnetic iron, from which considerable quantities have been extracted. It was discovered at Chester by Dr. Charles T. Jackson of Boston, and in Asia Minor, near Ephesus, by Dr. J. Lawrence Smith, an American mineralogist in the service of the Turkish government. Both discoveries are good examples of the value of accurate mineralogical knowledge.

Emery is scarcely inferior to the sapphire or ruby in hardness, and it will not only cut the hardest steel or chilled castings, but will wear away quartz, agate, topaz, and other gems, being for the last-named purpose the chief reliance of the lapidary. It was used by the ancients for cutting gems. Dioscorides mentions it under the name of *smyris* as the stone with which engraved gems are polished; and there is even a rabbinical tradition which indicates that the "smyris" was used for gem-engraving in the time of Moses. How far it was known and used in pre-historic times must be left to conjecture, but the many neatly cut and polished stone implements and ornaments indicate the use of a material not less hard than emery. Theophrastus mentions whetstones made of the mineral used to engrave gems, and cites Armenia as furnishing the best kind. Naxian whetstones are also mentioned by ancient authors, and Pliny speaks of polishing marble statues and *filing down* gems. The backs of antique intagli have deep furrows upon them, indicating that they were *filed* into shape by rubbing with an emery-stone. It is thus probable that the massive emery was extensively used as a tool, and that it was employed for the sculpture of hard rocks, not only by the Romans, but by the ancient Egyptians.

It is now used in the arts in a pulverized form, being obtained in grains or in powders of various degrees of fineness by crushing and sifting or by elutriation. The lumps, as they come from the mine, are broken in a breaker or under stamps, and the fragments are sifted through sieves or wire-cloth having from sixty to ninety wires to the inch, by which the grades of the emery are determined. Thus, a sieve of sixty wires to the inch gives a No. 60 grade. The numbers range as high as 120, or "flour emery." These higher numbers are obtained by washing, or by collecting the fine dust which floats in the air of the crushing-rooms and settles on the beams and shelves.

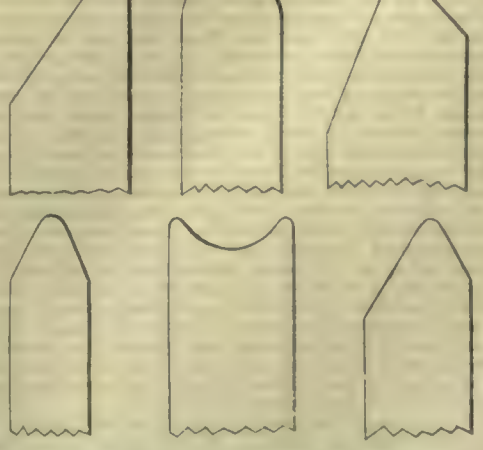
There is considerable difference in the effective abrasive power of commercial emery from different localities. It varies according to the composition, the state of aggregation, and the purity. The better qualities of crystalline corundum are believed to be superior to emery in abrasive powers, and powdered sapphire to be superior to corundum. But the experiments which are cited in support of this are by no means as complete and conclusive as they should be. The following shows the relative abrasive powers, as usually stated, of the sapphire, of corundum, and of emery from some of the principal localities: sapphire from India, 100; ruby, India, 90; corundum, Asia Minor, 77; emery, Kulali, 40 to 57; of Samos, 56; of Nicaria, 50; of Gumuch, 42 to 47; of Naxos, 46; of Chester, Mass., 43 to 45.

Sapphire contains 97½ per cent. of alumina, and corundum about 92 per cent. The percentage in emery ranges from 60 to 78, with 25 to 35 per cent. of oxide of iron, a few per cent. of silica and of water.

The methods of application are various. Lapidaries sprinkle it with water or oil on their lead-wheels. Mixed with glue or other adhesive substances, it is spread in a thin layer upon wood, leather, paper, or cloth, or it is moulded into solid blocks or wheels. It is in the latter form, known as "solid emery-wheels," that the mineral has the widest application and its greatest utility.

Emery-wheels.—Solid wheels, consisting of a mixture of powdered emery with shellac, fused and rolled upon a stick, appear to have originated with the lapidaries of India. Small wheels of a few inches only in diameter have been in common use for many years, especially by dentists for shaping hard porcelain teeth, but they are now made by improved methods from one to thirty-six inches in diameter, and from one quarter of an inch to four inches in thickness. When carefully mounted upon a mandril and run at a high speed, the abrading power of such wheels is wonderful. They will instantly take the teeth off the hardest file and reduce it to a plane, smooth surface, or will cut away parts of chilled castings that a file will not touch. Such wheels are shaping tools of the first order, as far exceeding files in efficacy as the emery exceeds steel in hardness, and as the velocity of a wheel exceeds the velocity of a file upon the work. A file in the hands of an expert workman moves, say, 60 feet in a minute, but the proper velocity of an emery-wheel at its cutting surface is 5500 feet in a minute. It is evident that such wheels are destined to replace files wherever they can be brought to bear upon the work. The grains of emery are the cutting points or teeth, and do not grow dull although brought into contact with metal hard enough to turn the teeth of a file at one stroke.

The rapidity of abrasion depends not only on the velocity of movement, but upon the size of the grains of emery. For very heavy work, such as taking the rough edges off castings, very coarse emery is used, while the finer sorts are made into wheels for fine grinding and surface-work on brass or steel. The following table shows approximately the cuts of emery as compared with files. The numbers represent the standard grades of emery:



Nos. of Emery.				
8–10	represents	the cut	of a	wood rasp.
16–20	"	"	"	rough file.
24–30	"	"	"	middle-cut file.
36–40	"	"	"	bastard file.
46–60	"	"	"	second-cut file.
70–80	"	"	"	smooth file.
90–100	"	"	"	superfine file.
120–flour emery		"	"	dead-smooth file.

The Tanite Company make five general classes of wheels: Class No. 1, coarse-hard; Class No. 2, medium-hard; Class No. 3, medium-soft; Class No. 4, fine-hard; Class No. 5, fine-soft.

In using emery-wheels care must be taken to maintain the proper speed, and not to press the work too strongly against the surface. If too much pressure is used, the wheels will not cut so fast, and are liable to wear away unequally and to get out of true. A rest should always be used to support the work and prevent it from vibrating upon the wheel. The bearings should be kept in good order and well lubricated.

Much attention is now given to the manufacture of machines for mounting emery-wheels. The mandrils are made of steel very carefully turned and fitted to the boxes, and frequently two or more wheels are mounted on the same mandril. The edges of the wheels are variously shaped to suit the work for which they are designed. Manufacturers now use them not only for trimming and shaping castings, but for shaping and sharpening hardened steel tools, such as the knives of planes and of wood-moulding machines, and for gumming saws. For the latter purpose they are particularly well adapted, and save time, labor, and files.

The following are outlines of some of the forms of the faces of emery-wheels:

Good emery-wheels are uniform in texture. The material with which the emery is combined must have great cohesive strength to resist the tendency of the wheels to fly asunder when revolving at high speed, and to retain the grains of emery firmly, and yet wear away evenly, leaving the cutting angles exposed, and not glaze or "gum up." It must not soften or melt under the heat generated

by the friction in cutting the work, and must be free from noxious qualities. As such wheels are run at high velocities, they require to be very carefully and exactly hung, and to be kept perfectly true, so as to prevent vibrations. They should not "wedge" upon the mandril, or even fit it closely, for expansion by heat might burst the wheel, and the flanges at the side should not be too strongly screwed up. A wheel thirty-six inches in diameter may have 611 revolutions per minute, and one of twelve inches, 1800 revolutions. Although the emery is so extremely hard, diamonds will cut the wheels, and this gem in its crude or rough form is used as a tool to turn them true or to cut their faces into any desired form. W. P. BLAKE.

Emet'ic [Gr. ἐμετικός, from ἐμέω, to "vomit"], a medicine capable of causing the stomach to contract and discharge its contents through the œsophagus. Emetics are of two classes: (1) those which appear to stimulate the action of the muscular coat of the stomach directly by their presence, such as alum, cupric sulphate (blue vitriol), and zinc sulphate (white vitriol): they act promptly, and are hence very useful in some cases of poisoning; (2) those which enter the circulation, and cause emetic action by their operation upon the nervous centres. To this class belong ipecacuanha, tartar emetic, lobelia, bloodroot, and many others. They are in general arterial sedatives, and may cause profound and even dangerous disturbances if unskilfully used.

Emeu. See EMU.

Emigra'tion [Lat. *emigratio*, a "removal" or "departure" of one or more individuals], the transference of permanent abode from one country to another. Removal into a country is specifically designated as *immigration;* it of course presupposes emigration. (See CRUSADES, EXILE, EXODUS, TRANSPORTATION, SLAVERY.)

Whatever view we take of the origin of mankind, it is evident that the earth must have been almost wholly peopled by numerous emigrations. The story of the wanderings of tribes and races constitutes the chief part of the traditions of the nations of antiquity. A complete record of emigration would amount to a synopsis of the early history of almost every considerable nation of ancient and modern times. The movements of the Aryan and Semitic races took place on a large scale, leaving everywhere their traces in languages, customs, and religions. Among the first of recorded emigrations, though of doubtful date, was that led by the Hyksos or Shepherd Kings, proceeding from Arabia or Phœnicia, and gradually overrunning Egypt, then a seat of civilization. In the Exodus we have an account of the emigration of the children of Israel, given with great fulness of detail. One of the earliest of the long series of incursions of the uncivilized tribes of Asia was the great invasion of Cimmerians and Scythians (650 B. C.), which even threatened Egypt, but was turned back by Cyaxares, the founder of the kingdom of the Medes. (See MAN AND HIS MIGRATIONS.)

The Greeks, boasting their own origin from the sacred soil of Hellas, were pre-eminent among the ancients for encouraging systematic emigration. They planted their colonies far and wide along the Central Sea, and founded great cities not only throughout the Grecian Archipelago, but in Sicily, Italy, and Asia Minor, and even on Gallic shores, on the Iberian peninsula, and on the African coast. The Romans, accepting mythical traditions as eagerly as the Greeks, found their own origin in an emigration from ruined Troy. But the policy of Rome, unlike that of Greece, fostered no rival colonies, and the emigrations which marked the rise of her power were principally the flight or transportation into slavery of the inhabitants of cities and provinces that yielded to her sway. The forced emigration of the slaves and captives of conquest reaches vast proportions in ancient annals. It was, however, after the empire of Rome had reached its culmination that the great movement of barbarian nations began, which is without parallel in the history of emigrations. A brief sketch of this movement, which continued through several centuries, can merely give prominent dates and names. The multitudes of those barbarian hosts cannot be estimated; they have furnished the poet with his most appropriate comparison for the countless legions which issued from the nether abyss at Satan's command.

The southward emigration of the Goths from Gothland, or Northern Sweden, began A. D. 200; their first pressure in the empire was felt on the N. of the Euxine, and they soon crossed the Danube. By the middle of the century they had overwhelmed Greece. Meanwhile, the Franks and Alemanni moved down in vast hordes from Western Europe, the former crossing the Rhine and the latter pouring through the Rhætian Alps. These incursions were checked by the victories of Claudian, Aurelian, and Probus (270–282), but the Goths established themselves during the following century on the borders of the Euxine, and spread through Thrace toward Italy. Between 376 and 410 was the climax of the movement of Northern races. The Huns, a nation of Tartar origin, coming down from the Ural Mountains and the table-lands of Siberia under Balamir, established an empire at the expense of the Goths, whom they drove out of the countries N. of the Danube; the latter, soon afterwards marshalled under Alaric, after ravaging Greece, descended upon Rome, effecting its capture A. D. 410. During the same period the Vandals from between the Elbe and the Vistula, with the Sueves and Burgundians of kindred origin, and the Alans from the Caucasus, swept through Italy, and, thence withdrawing, through Southern France into Spain; the Burgundians alone stopping in the valleys of the Vosges, the rest, pressed by the Goths who followed them, finally reaching Andalusia. In 429, Moorish tribes from the base of Mount Atlas were ravaging Northern Africa; in 439 the Vandals and Alans from Spain, under Genseric, following in the path of the Moors, extended the kingdom of the Vandals over the southern shore of the Mediterranean, and then crossing into Italy, captured and sacked Rome in 455. During the rise of the Vandal kingdom the Huns under Attila (435–450) swept down on the western provinces, and made an irruption into Gaul, but being defeated at Châlons in 451, they afterward withdrew to the E. of the Carpathian range. After Attila's death (453) the bulk of the remaining Huns retired to the shores of the Volga. During the same period the Saxons from between the Baltic and the Elbe, with the Angles to the N. of them, and the Jutes of Jutland, became dissatisfied with their homes, and in 449 descended on the British coasts, establishing themselves on the island.

Before the year 470 the Slavi had overrun what are now Prussia, Poland, and Russia; about the middle of the sixth century this Slavic territory—and in fact the whole region from Franconia to the Caucasus, from Moscow to the Danube—was taken possession of by the Avars, a Tartar tribe. They unsuccessfully besieged Constantinople, and indeed from the sixth to the thirteenth century the Byzantine empire was a bulwark against the Asiatic races, and prevented their penetrating Europe except by paths N. of the Euxine or S. of the Mediterranean. Starting from Arabian deserts in 632, the tide of Saracenic invasion rolled over the Levant and Northern Africa, entering Spain in 711, and was checked on the Loire by Charles Martel in 732. The Saracens spread from the Indus to the Atlantic, from the Pyrenees to the African desert, from the Caspian to the Red Sea. They invaded Sicily in 826, and held that island 265 years. The date of their conquest of India is 1004. Within the century when Europe was saved from the sword of the Saracen by the valor of Charles Martel, the victories of Carloman and Pepin (791–796) dislodged the Avars, and they withdrew to the eastward. The Bulgarians, partly of Tartar extraction, entered on a portion of the deserted territory. The Magyars, a Finnish tribe from the Ural, about the year 855 united with the vanquished Avars, and spread in camps of 1,000,000 men over the Dacian plain. A century later, Otho defeated them, and they afterward settled on the Danube.

The Danish vikings in 852 effected a permanent settlement in Russia, but not till 980 did they become affiliated with the native Russ and Sarmatians. The incursions of the Danes on the British coasts began before 890; in 1016 Canute's kingdom included Denmark, Norway, and England. The Danish and Norwegian vikings that were afterward called Normans ravaged the French coasts during this period, and settled in great numbers in Normandy in 912; they effected the conquest of England in 1066, and by 1072 had overrun all the Italian provinces of the Greek empire.

From the ninth to the eleventh century the Tartars ravaged China. In 1050 the Uzzi and Cumani, of Tartar extraction, overran all Southern Russia; they kept possession for 170 years. From 1216 to 1250 the Mongols under Genghis Khan, starting from the frontiers of China, created an empire, at a cost of 14,000,000 men slain by the sword, that extended from the Pacific to the Adriatic and the Baltic, overrunning all Southern Asia and Eastern Europe. The Mongols were probably allied to the Huns. After their victory on the Kalka in 1224, they held Russia subject for two and a half centuries. In the latter part of the century, after the withdrawal of the Mongols from Hungary, its king invited immigration, and obtained many Italian, Flemish, and Saxon settlers. The empire of Tamerlane (1363–1405) again spread the Mongolian power over all Southern Asia; the conquest of Hindostan was effected in 1399, and Delhi afterwards became the capital of the Great Mogul. From 1616 to 1647 the Mantchoo Tartars overran and subjected China: expelled thence, they settled on the banks of the Volga in 1672, but withdrew in 1771.

The Crusades (1095, 1147, 1189, 1202, 1217, 1227, 1248, 1270), though involving great emigrations, created no permanent states.

The Ottomans had partially established themselves in Europe in 1356; by 1460 they had overrun Turkey. In 1550 the Turkish power was at its zenith, reaching from the Tigris to the Carpathian chain, from the snows of the Caucasus to the deserts of Abyssinia. The expulsion of the Mohammedans from Western Europe was an affair of centuries. They were driven out of Sicily in 1091; Valencia, 1238; Portugal, 1292; Granada, 1492.

From 1552 to 1577 the Russians pushed their conquests over the Mongolian races through two continents, and, crossing the Pacific to a third, effected settlements in North America, which in 1794 were estimated as containing 50,000 souls. The measures which culminated in the Revocation of the Edict of Nantes (1685) caused the Huguenot emigration from France, which numbered from 250,000 to 300,000 souls; Sismondi assigns even a higher figure. In 1739, India was subjected to a terrible invasion by the Persians; in 1765 the British conquest followed, and after it came a steady flow of Englishmen. The French emigration consequent on the Revolution of 1790, consisting of noble families, was entirely exceptional in this characteristic. The czars, beginning with Peter the Great, have made notable and successful efforts in inducing foreigners to form colonies within their domain; and the last important movement of emigration within Europe was after Napoleon's wars, when Russia, by liberal offers, obtained 250,000 settlers, principally from her Western neighbors. In the recent war between France and Germany (1870) 102,000 Germans were expelled from France, and after the war there was a large movement of the French population from Alsace and Lorraine, and subsequently an emigration thither from Germany.

There are evidences of extensive movements among the native populations of America before the advent of Columbus. The Esquimaux—or, as they call themselves, the Inuit—inhabiting the northern and north-western coasts of America, are of a race found at the N. in the eastern hemisphere. The North American tribes of the interior were nomadic, but have left few definite records of their wanderings; the Mound-Builders spread all over the Valley of the Mississippi and its tributaries, but did not reach the Atlantic coast, and the dates of their progress and extinction are alike unknown. The Shawanese within historic times moved down from the northern Alleghanies along their western slope, and penetrated nearly to the Gulf of Mexico. There are records of many of the great movements of the races in the southern portion of North America. Torquemada, among earlier, and Clavigero, among later historians, have shown that the Toltecs, who during 104 years were advancing into Mexico from a region to the N. W. of it, founded the kingdom of Toltecan in the latter part of the sixth century. A famine nearly destroyed this nation in 1052; it was replaced in the next century by the less-civilized Chichimecas, and in the century following by other races from the N. and N. W., including the Aztecs or Mexicans from California. During the supremacy of the Toltecs in Mexico, their fifth king invaded Guatemala, and there established a dynasty of Toltec sovereigns, of whom the eighteenth was reigning when the Spaniards arrived. In South America the Toupis emigrated from the northern borders of the Amazon, spread to the Caribbean Sea and most of its islands, and advanced southerly along the Atlantic coast to S. lat. 32°, penetrating inland to the headwaters of the Rio de la Plata; through all this vast region one native language was spoken. A darkness which even the genius of Prescott has failed to pierce hangs over the entry into Peru of the race that built the monuments around Lake Titicaca.

Ever since its discovery America has been the chief land of promise to the voluntary emigrant; it has also been the principal destination of the enslaved African. The early statistics of emigration to this continent, though fully equal in interest to those so abundantly compiled in respect to the U. S. in later years, are, unfortunately, few and fragmentary. The colonies of emigrants that were most successful were under the direction of English companies, formed to carry on the business as a commercial speculation. There was a sharp rivalry between the North American colonies in offering to remit taxes, to give land, implements, and in some cases money. As early as 1606 two companies were formed in England "to found establishments in Virginia:" they sent out 3570 persons in 1619–21. Up to 1624 the Virginia company had spent £100,000 and sent out 7000 persons, of whom only 2000 then survived the sickness and dangers of the new country. The colony in 1648 numbered 15,000 whites, 300 blacks; in 1660, total, 30,000. The neighboring colony of the Carolinas was insignificant at the time of a charter in 1662; it benefited by an act of Parliament in 1670, which sent to America thieves convicted of stealing cotton goods spread to bleach. By 1700 the whites of this colony numbered 5300; in 1724, about 14,000. Easy privileges for obtaining land attracted thither in 1745 many emigrants from Germany and Holland; in 1746 the Scotch prisoners taken at Culloden were sent thither. The population had risen to 64,000 in 1750; in 1765, to 40,000 white, and at least twice as many colored. The New England company, chartered in 1620, had territory from lat. 40° to 48°, and by 1640, 21,200 persons had emigrated thither in 298 ships, at an expense to the company of £192,000; and at that date the natural increase of the colony had given it an additional 20,000, but the passage of the Toleration laws in England at this time induced fully that number to return to the mother country. In 1722 the colony of Massachusetts contained more than 94,000 persons; most of the other colonies were much smaller. The Dutch settlements on the Hudson had less than 10,000 souls when surrendered to the English in 1664, but the Pennsylvania colony, of which a large proportion was from Germany, was of rapid growth, the immigration in a single year (1729) being 6200.

The number of emigrants to this country during the provincial period, after colonial settlement and before the war of independence, cannot be closely approximated. The U. S. bureau of statistics has gathered more accurate figures for recent years, but the estimates prior to 1820 are still uncertain. Dr. Seybert's "Annals" give 120,000 for the period between 1790 and 1810. Prof. Tucker estimates 1810 to 1820 at 114,000. It is, however, safe to reckon for the two periods together, 250,000. From 1820 to 1830 the numbers were 151,824; 1831–40, 599,125; 1841–50, 1,713,251; 1851–60, 2,598,214; 1861–70, 2,491,151; 1871–73, and three-quarters of 1874, 1,482,947. Total in 84¾ years, 9,286,812. Of these immigrants, about two-fifths were females; 4,400,000 came from the British Islands; 2,844,000 from Germany, Austria, and Hungary; 283,000 from France; 278,000 from Scandinavian countries; 242,000 from all the rest of Europe; 419,000 from British America; 159,000 from China; 560,000 not specified; 83,000 from the rest of America, principally Mexico and the West Indies. The arrival of several colonies of Mennonites from Russia, and the doubtful project of peopling Alaska from Iceland, are the most recent features of immigration in the U. S.

Most of the states of continental Europe claim some control over the emigrant after his departure, unless he formally disavows his allegiance. In general, these claims have not been regarded with favor by the U. S. government, which throws every facility in the way of the immigrant for becoming a citizen of the republic. The Homestead laws of the U. S., giving 160 acres to the actual settler on unclaimed public lands, the laws for the protection of emigrants during their passage, and organized State systems to provide for their subsequent welfare, have done much to ameliorate the hardships incident to an ocean-voyage and settlement in a strange land. The use of steam has greatly shortened the time of transit.

The emigration from the British Islands has long exceeded that of any other country; its climax has probably been reached, but is not indicated in its somewhat irregular increase from 2081 in 1815 to 310,612 in 1873; the total number in the interval, including both years, being 7,887,992. Dividing this interval into three periods of nearly 20 years each, we find the emigration in the first of these periods about a tenth, in the last of them about one-half, of the total. Nearly five-eighths of this emigration went to the U. S.; a fifth to Canada; a seventh to Australia and New Zealand. Between 1793 and 1838 there were 74,000 convicts transported to Van Diemen's Land. In 1837, 2664 emigrants selected Australia as their home; its attractions reached their height during the years of gold-discovery, the number of emigrants to that country and New Zealand amounting in 1852 to 87,881; 1853, 61,401; 1854, 83,237; total 1849–59, 550,000. The Irish famine in 1846 increased the emigration from the British Islands during several following years; in 1847 it reached 109,680 to British North America; to the U. S., 142,154.

Germany ranks next to the United Kingdom as a source of emigration, the two countries together contributing four-fifths of the numbers that reach the U. S.; the yearly arrivals from Germany surpassing those from Ireland in 1854 and ever since. The German emigration to South America during the present century has been very considerable, especially to Brazil.

France has supplied a goodly share of the settlers of America. The French emigration to Canada reached a maximum about 1670: after 1713 a census gave a population of 25,000; it was 60,000 in 1761, the date of the English conquest. The French colonies in other parts of America have not been very considerable in point of numbers, though

some of them have proved permanent; among these in the present century are a few in South America.

The emigration from the Spanish Peninsula to America cannot be accurately stated; in lieu thereof the following estimates of population during early years of settlement will be found of service. California (including "Old California") and New Spain contained under the Spaniards, according to Humboldt, 70,000 Europeans, 1,025,000 Creoles, 7000 negroes. From figures furnished by Humboldt and Navarro, the white population in Mexico in 1803 may be estimated at 1,000,000; in 1823 at 1,230,000, and the mixed and colored races at 1,870,000. A very doubtful estimate gives 100,000 whites in Guatemala and all Central America in 1778. According to Restrépo (secretary of state), after the loss of 400,000 lives in the war of independence (1825), there were about 600,000 whites in Colombia. The white population of Peru 1795–1803 was 142,000; negro, etc., 326,000. According to Don Cosmo Bueno, the total population of Chili in 1764 was 240,000; in the census of 1813 about one-fifth were white. Nieuhoff in 1647 records the employment of 40,000 slaves in Brazil; it was estimated that in 1776 there were 1,500,000 Christians in that country, which was certainly a mistake, the census of 1818 giving only 843,000 whites. At the latter date there were 2,089,000 blacks, principally slaves. In later years Brazil has greatly encouraged emigration. Paraguay in 1809 had only 5133 Europeans, according to Azara, in a population of 97,500; Buenos Ayres had perhaps twice that number. The provinces of the Rio de la Plata may be estimated, from the figures of Nuñez in 1825, as having of white, mixed, and black 400,000. The Argentine Republic has secured a large emigration within the third quarter of the present century, exceeding 40,000 in a year, of which Italians, Spanish, and French form the greater proportion. The Guianas were principally populated by slaves; Dutch Guiana for two centuries has had about 3000 whites; all the Guianas in 1825 had only 10,000 whites to 206,000 negroes.

Great variations have taken place in the populations of the West India Islands. Thus, in Cuba there were 18,400 Spaniards in 1517; 40,000 in 1656; only 26,000 in 1700; 96,440 in 1774; in 1827, 311,051 whites and 393,436 blacks. In Puerto Rico there were in 1802, 78,281 whites and 84,911 blacks; the number of both was nearly doubled by 1834. In Barbadoes there were 21,000 whites in 1656; in 1670, 50,000 whites and 100,000 blacks; these numbers had fallen in 1712 to 12,528 and 41,970, and the whites increased but little for a century. Jamaica when captured by the English in 1655 had 40,000 slaves; in 1659, 4500 whites; 1698, 2300; 1755, 12,000; 1805, 28,000; up to 1823, 890,000 slaves had been brought into the island.

Bandinel estimates the total number of slaves that reached America from 1517 to 1807 at 5,000,000 to 6,000,000. The coolie trade from British India has transported, principally to the islands and coasts of America, a number of substitutes for slaves, recently averaging 25,000 a year; they are nominally apprentices, and emigrate with the hope of returning to their native land. WILLIAM C. WYCKOFF.

Emil'ia [Lat. *Æmilia*, called after the celebrated Via Æmilia of the Romans], the ancient name of that part of Northern Italy which contains the larger part of the former duchies of Parma and Módena and the papal delegations of the Romagna, or the present Italian provinces of Parma, Piacenza, Módena, Reggio, Bologna, Ferrara, Forlí, Ravenna, and Massa-Carrara. The name was officially revived in 1859. Area, 8604 square miles. Pop. 2,273,812.

Eminence, a post-twp. of Logan co., Ill. Pop. 1362.

Eminence, a post-village of Henry co., Ky., on the Louisville Cincinnati and Lexington R. R., 26 miles W. of Frankfort. It has a woollen and a flouring mill, three churches (one colored), a bank of deposit, two colleges open to both sexes, two hotels, and one newspaper. The principal business is farming and stock-raising. The location is healthy, surrounded by a beautiful blue-grass region. There is a valuable mineral spring in the vicinity.

W. A. HOLLAND, ED. "CONSTITUTIONALIST."

Eminence, a post-village, capital of Shannon co., Mo., on Current River, about 120 miles S. W. of St. Louis.

Em'inent Domain'. Domain is the territory under the jurisdiction of a sovereign, and *eminent domain* the inherent sovereign power which the people or government retain over the estates or private property of individuals to resume or appropriate the same for public uses, and for public uses only. The difference between the power of taxation and the right of eminent domain should be carefully noted. Taxation proceeds upon the notion of contribution; it falls upon a class of persons, and is apportioned among them by rule. In the exercise of the right of eminent domain the state takes from an individual his property without reference to a burden imposed upon any other person. The right can be exercised in this country either by a State or by the United States. The power to decide whether the property should be taken for any public use rests with the legislature, and its discretion is not reviewable by the courts, though it is conceived that the judicial power has the right to determine whether the use itself is public rather than private. Were this not so, the legislature might, under the pretence of taking property for public uses, transfer one man's property to another.

It is not necessary, however, that the exercise of the power should benefit the entire public. It is enough if it promotes the industrial capacity or resources of a considerable number of inhabitants, or in any manner indirectly contributes to the general welfare. It is not necessary that the State should act directly. The power may be delegated to a municipal body or to a private corporation. A State may delegate it to the United States. The mode of exercising it is regulated by constitutional provisions and by statutes. In some cases only an easement in land is acquired; at other times the entire fee is appropriated. The constitutional prohibition (U. S. Constitution, Amendments, Art. V.) against taking private property for public use without just compensation is a limitation on the power of the Federal government, and not on that of the States. There are similar provisions in the State constitutions binding the State legislatures. The compensation includes not only the property actually taken, but consequential damages to adjoining property. This has recently been carried so far in England by the House of Lords as to hold that a riparian owner on the banks of a navigable stream (the Thames) is entitled to compensation for the act of cutting off his approach to the river, on the ground that the right of access to a tide-water stream is a legal right, which would justify an action by the owner against one who interfered with it, unless Parliament had sanctioned the interference. (*Case of the Duke of Buccleuch, Law Reports*, 5, *House of Lords' Cases*, 478, A. D. 1872.) Still, if *no* property is taken, a claim cannot be made for consequential damages. The same right to compensation as is secured in this country by constitutional provisions is recognized generally among civilized nations, and may be considered as a general rule in jurisprudence. T. W. DWIGHT.

E'mir, or **Emeer'** (written also **Amir** and **Ameer**), an Arabic word signifying "chief" or "ruler." The caliphs took the title of emir-al-Mumenin, "chief or commander of the faithful." The title is now given by prescriptive usage to those who are the real or reputed descendants of Mohammed through his daughter Fatima. Many independent chiefs of Northern Africa assume the title of emir. The word emir, joined to another word, occurs in several official titles, as emir-al-Omrah, formerly the title of the first minister of the caliphs and moguls, and at present sometimes the title of the pashas of large Turkish provinces.

Em'lenton, a post-village of Venango co., Pa., has one weekly newspaper.

Em'ly, a small town of Ireland, in the county of Tipperary, was formerly a bishop's see, which was united to Cashel in 1568.

Emman'uel [Port. *Manoel*], surnamed THE GREAT, king of Portugal, was born in May, 1469. He succeeded John II. May 3, 1495, and married Isabella, a daughter of Ferdinand and Isabella of Castile. He promoted education, maritime enterprise, and commerce. During his prosperous reign the power and glory of Portugal were increased by the discoveries and victories of Vasco da Gama, Albuquerque, and Almeida in India and Brazil. Portugal was probably the greatest naval power of the world in his reign, which constitutes the golden age of Portuguese history. His power and renown were greater than any Portuguese monarch ever possessed, either before or since his time; but he greatly injured his country by the banishment of all Jews and the enforced conversion of their young children. His third wife was Eleonore, a sister of the emperor Charles V., whom he married in 1519. He died Dec. 13, 1521, and was succeeded by his son, John III.

Em'men, a town of Holland, in the province of Drenthe, 31 miles S. E. of Groningen. Pop. in 1867, 5437.

Emmerich, ĕm'mer-rĭk', a walled town of Prussia, is on the right bank of the Rhine, about 50 miles N. N. W. of Düsseldorf and 20 miles S. E. of Arnheim, with both of which it is connected by a railway. It has a custom-house, gymnasium, and several churches; also manufactures of woollen cloth, linens, hosiery, etc. P. in 1871, 7817.

Emmet, a post-township of St. Clair co., Mich. P. 960.

Em'met (ROBERT), an Irish patriot and orator, born in Cork in 1780. He was devoted to the independence of Ireland, and was a leader of the United Irishmen, who desired to liberate their country from British domination. Having secretly collected arms and powder in Dublin and formed a conspiracy, he and his friends revolted in July, 1803.

The insurgents killed the chief-justice, Lord Kilwarden, but were soon dispersed by a party of soldiers. Emmet was arrested and tried for treason. He pleaded his own cause in a long and very eloquent speech, which has been preserved, but he was convicted and executed Sept. 20, 1803. His fate and his affection for Miss Curran are the subjects of two of Moore's "Irish Melodies."

Emmet (Thomas Addis), LL.D., an Irish lawyer, a brother of the preceding, was born in Cork in 1764. He was a leader of the United Irishmen, and as such was arrested in 1798, and confined in prison for nearly three years. His sentence was commuted into exile, and he emigrated in 1804 to New York City, where he practised law with distinction. He was elected attorney-general of the State of New York in 1812. He was an eloquent advocate, and had great qualities as an orator. Died in New York Nov. 14, 1827.

Emmett, a county in the N. N. W. of Iowa. Area, 450 square miles. It is intersected by the West Fork of the Des Moines River, and contains several small lakes. Grain and wool are raised. Capital, Estherville. Pop. 1392.

Emmett, a county of Michigan, which forms the extreme northern part of the Lower Peninsula. It is bounded on the N. W. by Lake Michigan, from which Little Traverse Bay extends into the southern part of the county. Grain and potatoes are staple products. Capital, Little Traverse. Pop. 1211.

Emmett, a township of McDonough co., Ill. P. 957.

Emmett, a post-township of Emmett co., Ia. P. 232.

Emmett, a township of Calhoun co., Mich. Pop. 1309.

Emmett, a township of Dodge co., Wis. Pop. 1375.

Emmettsburg, a post-village, capital of Palo Alto co., Ia., on the Des Moines River, 55 miles N. N. W. of Fort Dodge and 25 miles W. of Algona. It is the only village in the county, and is a thrifty business-place. It has a saw-mill and a flouring-mill, and is the proposed junction of the McGregor and Missouri River R. R. with the Des Moines Valley R. R. Both are surveyed, and have land-grants through the county, and considerable grading has been done on the former. It has one weekly newspaper. Pop. in 1870 of village, 44; of township, 316.

Ed. "Advance."

Emmettsville, a village of Greene township, Randolph co., Ind. Pop. 67.

Emmittsburg, a post-village of Frederick co., Md., 8 miles N. of Mechanicstown, 1 mile from Mason and Dixon's Line, and 10 miles from Gettysburg, Pa. It was laid out by William Emmitt, its founder, about the year 1773. The original population were Scotch and Irish. Mount St. Mary's College was established near it in 1809 by Rev. John Dubois, late bishop of New York; it is a Roman Catholic institution, one of the largest in the U. S. There are 200 students at present in attendance. Rev. John McCloskey (brother of the present bishop of New York) is the president of the institution. St. Joseph's Academy, about half a mile from town, was established in 1810, by Mrs. Eliza Ann Seton of New York. It is the mother-house of the Sisters of Charity in the U. S., and numbers 2000 members, and has the largest educational building in Maryland, perhaps in the U. S. There are $1,500,000 surplus in the treasury. There are five churches in the village. Pop. 706; of township, 3168.

Wm. Need, Ed. "Catoctin Clarion."

Emmon's, a township of Davidson co., N. C. P. 941.

Em'mons (Ebenezer), M. D., an American geologist, born at Middlefield, Mass., May 16, 1799. He became in 1833 professor of natural history in Williams College. He was one of the geologists selected by the governor of New York in 1836 to make a geological survey of that State. In 1838 he became professor of chemistry in the Albany Medical College. In 1856 he became State geologist for North Carolina, where he remained until his death. He wrote several reports, which were published in the "Natural History of New York;" also a report of the quadrupeds of Massachusetts, three reports of the geology of North Carolina, and several text-books on mineralogy and geology. Died Oct. 1, 1863.

Emmons (George F.), U. S. N., born Aug. 23, 1811, at Clarendon, Rutland co., Vt., entered the navy as a midshipman April 1, 1828, became a passed midshipman in 1834, a lieutenant in 1841, a commander in 1856, a captain in 1863, a commodore in 1868, and a rear-admiral in 1872. He served in the South Sea exploring expedition from 1838 to 1842, and on the west coast of Mexico during the war with that country. In the early part of our civil war he was in command of various vessels of the Gulf blockading squadron and Admiral Dahlgren's fleet, and was captain for some months in 1863 during the operations against Fort Sumter. From 1864 to the close of the war he commanded a division of the blockading fleet in the Gulf of Mexico.

Foxhall A. Parker, U. S. N.

Emmons (Nathanael), D. D., one of the most eminent of American theologians, was born April 20 (O. S.), 1745, at East Haddam, Conn., and graduated with honor at Yale in 1767. He was ordained pastor of the Congregational church in Franklin, Mass., in 1773, and was its pastor until his death, and its sole pastor for fifty-four years. In addition to his pastoral labors he trained nearly one hundred young men for the ministry, many of them afterwards eminent. He was also a prominent advocate of foreign missions and of the anti-slavery cause. His theological views were nearly those of his friend Dr. Samuel Hopkins, and his sermons, distinguished by logical thought and by dignity and power of style, were in many instances characterized by ingenious efforts at solving the problems suggested by the doctrines of the Divine government and the freedom of the human will. Died Sept. 23, 1840. His works (sermons, essays, etc.), published at different times during his life, were after his death published (1842) in seven and afterwards (1861) in six volumes octavo, with memoirs of his life, in the first edition by J. Ide, D. D., and in the second by Prof. E. A. Park.

Em'ory, a township of Stanislaus co., Cal. Pop. 843.

Emory, a post-village, capital of Rains co., Tex. It is very near the geographical centre of the county.

Emory, a post-village of Washington co., Va., on the Atlantic Mississippi and Ohio R. R., 10 miles E. of Abingdon. It has one newspaper, and is the seat of Emory and Henry College, which is sustained by the Methodist Episcopal Church South. There are two hotels and five or six churches in the immediate vicinity.

C. M. Brown, Ed. "Banner."

Emory (John), D. D., an eminent writer and bishop of the Methodist Episcopal Church, born in Queen Anne co., Md., April 11, 1789, was educated a lawyer, became a Methodist preacher in 1810, preached extensively for many years through the Middle States, and was sent as delegate of his denomination, in 1820, to the British Wesleyan conference. He was appointed in 1824 book agent at New York, and elected bishop in 1832. Died Dec. 16, 1835. In 1817 he had a pamphlet controversy with Bishop White of Philadelphia. He was author of "The Divinity of Christ Vindicated," "Defence of Our Fathers," and other publications, which show much logical ability and a pure and vigorous style.

Emory (Robert), D. D., son of the preceding, an eminent divine and educator of the Methodist Episcopal Church, born in Philadelphia July 29, 1814, was president of Dickinson College, Carlisle, Pa., and author of the "Life of Bishop Emory" and "History of the Discipline of the Methodist Episcopal Church." Died May 18, 1848.

Emory (William H.), an American officer, born in 1811 in Queen Anne's co., Md., graduated at West Point in 1831, colonel Fifth Cavalry Oct. 27, 1863, and Sept. 25, 1865, major-general U. S. Volunteers. He served as lieutenant of artillery and of mounted rangers till he resigned, Sept. 30, 1836; chiefly at sea-board posts, 1831–36; in Charleston harbor, 1832–33, during the threatened nullification of South Carolina; and in the Creek nation, 1836–38. He was appointed first-lieutenant topographical engineers, July 7, 1838, and major of cavalry Mar. 3, 1865, serving on Delaware river improvements and in topographical bureau, 1839–44; on north-east boundary survey, 1844–46; in the war with Mexico, 1846–48, on the staff of Brigadier-General Kearny; engaged in the actions on his march to California (captain and brevet major); as lieutenant-colonel Maryland and District of Columbia Volunteers; as astronomer of boundary between California and Mexico, 1848–53, and commissioner and astronomer, 1854–57 (brevet lieutenant-colonel); in suppressing Kansas disturbances and on Utah expedition, 1858, and on frontier, board, and inspection duties, 1858–61. He resigned May 9, 1861, and was reappointed May 14, 1861. He was lieutenant-colonel of Sixth Cavalry, serving in Virginia peninsula, 1862; engaged at Yorktown, Williamsburg, and Hanover Court-house (brevet colonel); in department of the Gulf, 1862–63, engaged at Port Hudson, Camp Bisland, Lafourche Crossing, and Donaldsonville; in Red River campaign, 1863–64; engaged at Sabine Cross-roads, Pleasant Hill, and Cane River; in command of Nineteenth Corps, 1864–66; engaged at Marksville, defence of Washington, D. C., Opequan, Fisher's Hill (brevet brigadier-general), Cedar Creek (brevet major-general); in command of department of West Virginia 1865–66, of department of Washington 1869–71, and of department of the Gulf 1871–75; retired with rank of brigadier-general 1876. George W. Cullum, *U. S. Army.*

Emory College is in Oxford, Newton co., Ga., 40 miles E. of Atlanta, and 1 mile from the Georgia R. R. Its literary, social, and religious advantages are of the highest order. It was chartered in 1837, and was opened to students in 1838, under the presidency of Rev. Ignatius A. Few, D. D., LL.D. It is under the control of the Methodist Episcopal Church South. The sons of itinerant preachers in the States of Georgia and Florida are educated free of tuition fees. The curriculum of study embraces Latin, Greek, mathematics, natural science, with mental and moral science, evidences of Christianity, belles lettres, and the English Bible. There is also a scientific course, which embraces all of these branches except Latin and Greek. The number of graduates from July, 1841, when the first class graduated, to July, 1873, is over 500, about 20 per cent. of whom are ministers of the gospel, and a still larger percentage has been devoted to the work of teaching. The faculty of the college embraces six professors, and it has the usual appliances for thorough and efficient instruction, such as library, cabinet, philosophical and chemical apparatus. The literary societies have good halls, well furnished, and good libraries and reading-rooms. The college has been under the presidency of the following named gentlemen: Rev. Ignatius A. Few, D. D., LL.D., Rev. A. B. Longstreet, LL.D., Rev. Bishop George F. Pierce, D. D., LL.D., Rev. A. Means, D. D., LL.D., Rev. J. R. Thomas, D. D., Rev. Luther M. Smith, D. D., and Rev. O. L. Smith, D. D. The trustees of the college are now erecting new lecture-rooms and a new and commodious chapel, proposing to afford advantages equal in all respects to those of any institution of like grade in the land. The average number of students for the last few years has been about 200. Two hundred and fifty dollars per annum will cover all expenses of board, tuition, and books. O. L. Smith.

Emo'tion [from the Lat. *e*, "out," and *moveo, motum*, to "move," hence to "feel"] is a psychological term which may be most easily explained by its relation to that of *sensation*. A *sensation* is simply the consciousness of a peculiar state of the body, pleasurable or painful; which consciousness reacts on the body purposing to continue or discontinue its present state. When, for some reason or other, no such reaction takes place, but the consciousness of a certain state of the body flows over into the imagination, the *sensation* becomes an *emotion;* when it passes into the intellect, it becomes a *cognition*.

Empan'nel, or **Impannel,** to enrol a list of jurors; to write a list of the names of men who shall serve as jurors in any trial. The sheriff summons a number of persons, and prepares lists called the panels of the jury.

Emped'ocles [Gr. Ἐμπεδοκλῆς], a celebrated Greek philosopher, born at Agrigentum in Sicily, lived about 450 B. C. He acquired great fame and influence by his talents and varied attainments in science. It is said that his fellow-citizens offered him the crown, but he declined it, and used his influence to found a republic in his native state. He was regarded as a public benefactor, a great poet, and a predicter of futurity. He maintained the theory that the world is developed or compounded from four primary elements, fire, air, earth, and water. He wrote, besides other works, a poem on "Nature," of which fragments are extant. It appears that he accepted the doctrine that the souls of some men, at least, are destined to migrate through animal or vegetable bodies in order to purify them. The tradition that he threw himself into the crater of Mt. Etna to immortalize his name is not generally credited. He was admired by Aristotle and Lucretius, the latter of whom eulogizes him in his poem "De Rerum Naturâ." The fragments of Empedocles have been edited by Stein (1852) and others. (See Ritter, "History of Philosophy;" Gladisch, "Empedocles und die Aegypter," 1858.)

Em'peror [Lat. *impera'tor*, from *im'pero*, to "command;" Fr. *empereur;* Ger. *Kai'ser*], the sovereign who rules over an empire. The title *imperator* was conferred by the ancient Romans on their consuls in their military capacity, after this authority had been confirmed to them by the *comitia curiata*. The signification of imperator depended on that of *imperium*, which was the name given to the supreme power of the senate and people of Rome over the city and subject provinces. An officer clothed with authority by law exercised this imperium within the limits and time of his command. After any great victory the soldiers were accustomed to salute their commander as imperator as a compliment, though, as exercising the imperium attached to his command, he was already such in fact. He might be a consul or a proconsul, and the imperium was as necessary for a governor of a province as for a general who merely commanded an army. Under the republic there might be many *imperatores* at one time. On the subversion of the republic the title was conferred on Augustus for life. The authority of the Roman emperors was acquired by the combination of the chief offices of the former republic in a single person; besides which, some extraordinary powers were granted or usurped. Thus, Octavius held the title of imperator and the office of consul by successive elections. He was made tribune, which gave inviolability to his person, and pontifex maximus and censor, which gave him control of religion and morals. He was also invested with perpetual proconsular authority, which gave him supreme control in all the provinces, and declared chief (*princeps*) of the senate, and Augustus, which last designation was assumed by his successors. The title imperator was assumed by the emperors on the occasion of victories of themselves or their armies. Aurelius is represented on a coin as imperator for the eighth time. With the early Roman emperors the term imperator did not denote the sovereign power. It is not easy to determine at what time the word came to be used in the modern sense of emperor as the proper name for the sovereign of the Roman state. The term *princeps* was used as a convertible term with it. The Roman emperors appointed their own successors, who received the title of cæsar during the life of the emperor who appointed them. After the court was removed to Constantinople, the old titles and forms of the republic gradually vanished, and the emperors assumed the style of Oriental princes. The title of emperor of the Romans was conferred on Charlemagne by Pope Leo III. in 800 A. D., and was borne by his successors until the dissolution of the Holy Roman Empire in 1806.

On the 18th of Jan., 1871, King William I. of Prussia assumed the title of emperor of Germany at the request of all the German princes. Napoleon I. assumed the imperial style in 1804, and Napoleon III. in 1852. The latter was deposed after the battle of Sedan on the 4th of Sept., 1870. After the Greek empire had been divided into two parts in 1204, the rulers of both parts continued to bear the title of emperor, the Latin emperor residing at Constantinople, and the Greek emperor at Nicæa. In 1263 the two parts were reunited, and in 1328 the Greek empire was again divided into the empire of Constantinople and that of Trebizond. After the Turks had conquered these empires, the sultans assumed the title of emperor, which was recognized by the European powers in 1606. Czar Peter I. of Russia assumed the imperial title in 1721. After the dissolution of the Holy Roman empire in 1806 the rulers of Austria assumed the title of emperor of Austria. Outside of Europe there is at present only the empire of Brazil, though the British possessions in Asia constitute the "Indian empire," and the sovereign of Great Britain has the title of emperor of India. Several attempts have been made to establish other empires in America, but all have failed. In Mexico, Iturbide assumed the title of emperor in 1822, and Maximilian of Austria in 1864. In Hayti the negroes Christophe in 1811, and Soulouque in 1849, reigned for a short time as emperors, but were soon deposed. The rulers of Morocco, China, and Japan are also sometimes called emperors. The modern idea of an empire in general seems to be a union of states, each with a local government, under the protection or political preponderance of one powerful state. The personal sovereign of such a state may by conquest or election become the emperor, sustaining a special governing relation to his own hereditary dominions, and a general control as emperor over the confederated, yet subordinate, states of the empire. But there is a tendency towards a looser use of the term as a mere title of the head of a kingdom.

Emperor Moth (*Saturnia pavonia minor*), the largest British lepidopterous insect, is allied to the silkworm moth, and belongs to the Bombycidæ. Its wings when expanded measure three and a half inches, each wing having a large transparent spot. The peacock moth (*Saturnia pavonia major*) is five inches across the wings, being the largest species in Europe. Silk is obtained from cocoons of certain species of this genus.

Em'phasis [Gr. ἔμφασις, a "setting forth," from ἐμφαίνω, to "show;" Fr. *emphase*], in elocution, the stress laid on particular words or syllables in a sentence in order to express or enforce an idea or a meaning; sometimes a peculiar impressiveness or earnestness of expression.

Emphyse'ma [from the Gr. ἐν, "in," and φυσάω, to "flow," to "puff up"], in pathology, an inflation produced by air or gas in the cellular tissue. Emphysema of the lungs is owing to dilatation of the air-vesicles.

Emphyteu'sis [Gr., from ἐν, "in," and φυτεύω, to "plant" or "graft"] is a contract in civil law by which lands or tenements are given to be possessed for a long term or for ever, and an annual rent (*canon emphyteuticus*) in money, grain, etc. reserved and made payable to the grantor, in recognition of his paramount title. The grantee acquires the *dominium utile* or usufruct, while the grantor reserves the *dominium directum*. The Scottish grant in feu-farm is

similar to the emphyteusis. The word fief is supposed to have been derived from emphyteusis.

Empire. See Emperor.

Em'pire, a township of Stanislaus co., Cal. Pop. 2993.

Empire, a township of McLean co., Ill. Pop. 2133.

Empire, a post-township of Leelenaw co., Mich. Pop. 450.

Empire, a post-township of Dakota co., Minn. P. 995.

Empire, a post-township of Fond du Lac co., Wis. Pop. 1055.

Em'pire Cit'y, a post-village of Clear Creek co., Col., is on Clear Creek, about 48 miles W. of Denver. It is surrounded by high mountains. Here are gold and silver mines.

Empire City, a post-township of Ormsby co., Nev. Pop. 626.

Empire City, a thriving post-village, capital of Coos co., Or., is on Coos Bay, 130 miles S. S. W. of Salem. Excellent lignitic coal is exported.

Empir'ic [Gr. *ἐμπειρικός*, "experienced;" Lat. *empiricus*; Fr. *empirique*], one whose knowledge or skill is founded on experience or experiment. In the time of Celsus and Galen there was a medical sect called *Empirici*, supposed to have originated with Philinus of Cos and Serapion. These empirics were opposed to the *Dogmatic* sect or school, and considered that medical science should be based on experience rather than theory. They became so notorious for ignorance that the term empiric is now generally applied to quacks and practitioners who are ignorant of medical science. In its application to philosophy empiric denotes one who depends for truth entirely upon sensual experience, independent of those limitations of the mind's constitution which condition and supplement it. Empiricism is a name applied by many of the German schools of philosophy to the system which may be called that of observation and induction, relying upon phenomena which are made evident in consciousness. They apply the term to the methods of Locke, Reid, and Stewart, without properly discriminating them from the materialists, to whom the term, in both ancient and modern times, has been legitimately applied.

Empir'ical Laws are expressions which set forth a general relationship in any class of phenomena, without attempting to explain the principle underlying that relationship. The underlying principle may, in fact, be unknown, as in the case of Bode's Law (which see). Bode's law is one of the most remarkable of all the empirical formulas known to science.

Empiricus. See Sextus Empiricus.

Em'poli, a town of Italy, in the province of Florence, is on the river Arno, 16 miles W. of Florence, with which it is connected by a railway. It is in a beautiful and fertile district, is well built, and has an interesting church, which was founded in 1093, and is adorned with paintings by Giotto. Here are manufactures of cotton fabrics, straw hats, etc. Pop. in 1861, 5805.

Empo'ria, a post-village, capital of Lyon co., Kan., near the Atchison Topeka and Santa Fé R. R. where it crosses the Missouri Kansas and Texas R. R., 61 miles S. S. W. of Topeka. It is between the Neosho and Cottonwood rivers, 6 miles above their junction, in a fine agricultural and stock-raising region. It has a large trade, and is one of the best-built towns in the State. It is the seat of the State normal school, with a fine large building and 250 students. It has a court-house, two national, one private bank, two newspapers, flouring-mill, furniture, soap, and carriage factory. Pop. 2168; of Emporia township, 1182. Jacob Stotler, Ed. "Emporia News."

Emporium, a post-village, capital of Cameron co., Pa., at the junction of the Buffalo New York and Philadelphia R. R. with the Philadelphia and Erie R. R., 99 miles W. N. W. of Williamsport. It has three newspaper offices and an important lumber-trade. Valuable salt-wells abound in the vicinity. Pop. 898.

Empyreu'ma [Gr. *ἐμπύρευμα*, from *ἐμπυρεύω*, to "kindle"], the odor emitted by animal and vegetable substances when they are burned or decomposed by a strong heat. The oils obtained by the destructive distillation of organic substances at high temperatures are called *empyreumatic oils*.

Ems (anc. *Ami'sia* or *Ami'sius*), a river of Germany, rises in Prussian Westphalia, near Paderborn. Its general direction is northward. After a course of about 200 miles it enters the Dollart, an inlet of the North Sea, near the town of Emden. It is connected by a canal with the Lippe.

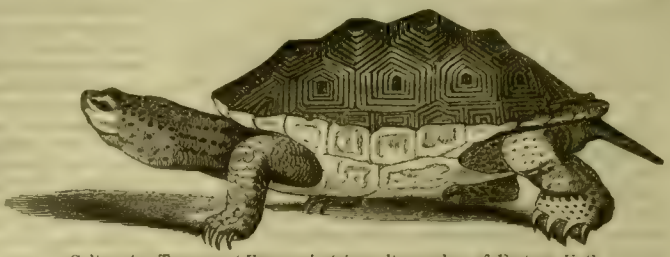
Ems, or **Bad-Ems** (*i. e.* "bath of Ems"), a celebrated watering-place of Germany, in the Prussian province of Hesse Nassau, on the river Lahn, about 7 miles S. E. of Coblentz. It is surrounded by picturesque scenery, and is situated in a beautiful valley among wooded hills. Here are warm mineral saline springs, the temperature of which varies from 93° to 135° Fahrenheit. It has good hotels, and is frequented by many visitors, including English and other foreigners. Pop. in 1871, 5458. In 1785 the archbishops of Treves, Mayence, Cologne, and Salzburg formed an agreement here, called the "Punctation of Ems," in which they demanded in twenty-three articles the change of several papal privileges in favor of the German archbishops. The real object, however, was the establishment of a national German Church. But in consequence of the opposition of their own bishops and the firmness of the pope, they were compelled to submit to the authority of the pope within a year. On July 13, 1870, the French ambassador, Count Benedetti, had at Ems the famous interview with King William of Prussia which precipitated the outbreak of the great war between France and Germany.

Em'ser (Hieronymus), a German Catholic theologian and adversary of Luther, born at Ulm Mar. 26, 1477. He was secretary to George, duke of Saxony. He issued (1527) a translation of the New Testament, which he called his own, but which is only a copy of Luther's, with some unimportant verbal alterations. Died Nov. 8, 1527.

E'mu, or **E'meu** (*Dromaius Novæ Hollandiæ*), a large Australian bird, belonging to the Struthionidæ and allied to the ostrich and cassowary. It differs from the latter in being taller, having the bill horizontally depressed, and in being destitute of the bony crest and pendent wattles. When full-grown it is of a brown color, mottled with gray. It has only rudimentary wings, but is exceedingly fleet in running. The eggs are dark green, and about seven in number. Both the eggs and flesh are esteemed excellent for the table. Its plumage is long and almost hair-like. The plumes are readily dyed of various colors, and appear to some extent in commerce as a substitute for ostrich feathers. It has become rare in the more settled parts of Australia, having been hunted for the sake of its oil, which the skin contains in large quantities. It feeds mostly on fruit, herbage, etc., and is easily domesticated.

Emu.

Emu Wren (*Stipiturus malachurus*), a passerine bird of Australia, nearly allied to the wrens of Europe and Amer-

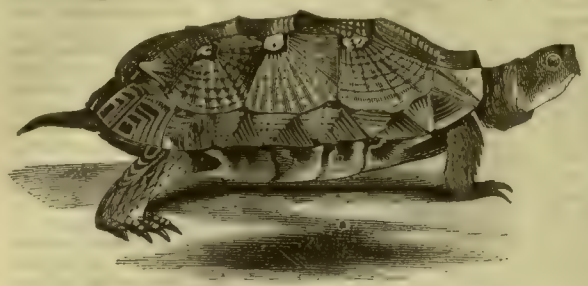


Emu Wren.

ica. The genus includes about a dozen Australian species. This bird haunts marshy districts, never alighting on high trees, and seldom taking to flight, but running rapidly about the grass with its long tail-feathers erect. It takes its name from these feathers, which are six in number, and have a real or fancied resemblance to the feathers of the emeu.

Emul'sin (*Synaptase*), an albuminous substance found in almonds, which acts as a ferment upon the glucoside amygdalin of bitter almonds, transforming it into bitter almond oil (hydride of benzoyl), hydrocyanic (prussic) acid, and glucose (grape sugar).

Emul'sion [from the Lat. *emul'geo*, to "milk"], the name of a liquid preparation resembling milk in color and consistence, and obtained by mixing oil and water by means of some other substance, mucilaginous or saccharine. Emulsions are useful in pharmacy.



E'mys [Gr.], a genus of chelonians or fresh-water tortoises. They differ from land-tortoises in having the feet more webbed and expanded, and the shell of the back more flattened. The painted tortoise (*Emys picta*) and alligator tortoise (*Emysaura serpentina*) are abundant in North America. Several species are natives of Southern Europe. DeKay makes the genus to include nearly all the fresh-water species in America, including fifteen or twenty in the U. S. They are generally known as terrapins, and many of them are prized for the table. Fossil remains of the genus are found in the eocene.

Salt-water Terrapin (*Emys palustris*), salt marshes of Eastern U. S.

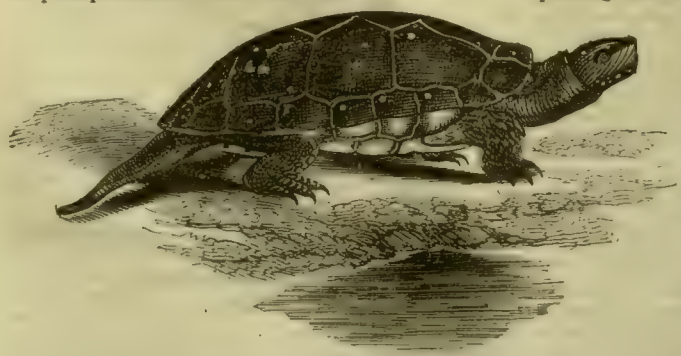
The little spotted tortoise (*Emys guttata*), from five to nine inches long, is found throughout a great part of the U. S., is black, with roundish speckles or spots above, and is black and yellow beneath. It is sometimes caught on the land.

The salt-water terrapin (*Emys palustris*) is from five to seven inches long, being found in brackish tidal waters and salt marshes of our Atlantic coast, especially northward. It is one of the most highly prized of the terrapins. It is dug out of the mud in winter, when it is very fat, and marketed in considerable numbers for table use. Many other terrapins are known in the U. S., especially southward and westward.

Wood Terrapin (*Emys insculpta*), U. S. and Canada.

Enaliosau'rians [from the Gr. ἐνάλιος, "marine" (ἐν, "in," and ἅλς, the "sea"), and σαῦρος, a "lizard"], a group of extinct saurians having paddles for swimming instead of true feet, and having crocodilian teeth and biconcave vertebræ like those of fishes. Their remains first appear in the carboniferous rocks, and disappear in the cretaceous, being most numerous in the Jurassic strata. They appear to have been mostly or all marine. *Ichthyosaurus* is one of the most important of the genera.

Enam'el [Fr. *émail*, from the Late Lat. *smal'tum*, "smalt," the blue color of enamel], a name given to various opaque or semi-opaque glasses used in glazing or finishing the surface of pottery, iron, and jewelry. Common glass fused with oxide of antimony or tin becomes a white enamel; oxide of cobalt produces a deep blue; manganese, an amethyst; cuprous oxide, a ruby-red; cupric oxide, green, etc. The hard external layer of the teeth is called "the enamel;" it contains a large percentage of oxide of lime.



Red-bellied Terrapin (*Emys rubriventris*), found about New York.

Enamelled Leather, leather the surface of which is rendered glossy by successive coats of linseed oil, and finally of a varnish of copal and asphaltum. (See LEATHER.)

Enamel Painting, the art of applying artistic painting to glass, pottery, or the metals, most glass-staining at present being simply enamel painting. The various colors (chiefly oxides of lead, platinum, gold, titanium, uranium, chromium, etc.) are mixed with some glass or "flux," ground, made into a paint with oil of spike or some other volatile oil, and then applied with a soft brush, the outline being usually first applied, and then burnt in at a great heat in a glowing muffle. Afterwards the outlines are filled up by repeated paintings and burnings, different colors requiring different treatment. Some faint idea of the needed skill may be formed from the fact that the painter has to work not with actual colors, but with substances which he knows will produce these colors after firing. Nevertheless, delicate shades and shadows can be thus produced, and there have been many famous and accurate enamellers of portraits. This art was well known in ancient Egypt and Etruria, and in mediæval times its use, derived from Byzantine and Moorish workmen, became common in France and Italy.

The wood terrapin (*Emys insculpta*), found in the U. S. and Canada, is eleven inches long, of a reddish-brown color, with radiating lines of yellow. It is found in fresh waters, but perhaps oftener in fields and woods.

Spotted Tortoise (*Emys guttata*), U. S.

The red-bellied terrapin, common in the New York markets, is from ten to seventeen inches long, dusky in color, with reddish marks, and is red beneath. Its flesh is very good.

Enara, or **Enare,** a large lake of Russia, in Lapland, about lat. 69° N. and lon. 28° E. Area, 1050 square miles.

Enarea, a country of Africa, in Abyssinia, lies S. W. of Shoa. Its limits have not been accurately ascertained. It is mostly included between lat. 7° and 9° N., and is inhabited by Gougas. The chief exports are ivory, slaves, and

coffee, the last of which is cultivated extensively. Capital, Sukka.

Enarthro'sis, the name given in anatomy to that kind of articulation which permits the widest range of motion. It is known as the ball and socket joint, and is formed by inserting the round end of one bone in the cavity of another, as in the hip and shoulder.

Encamp'ment [Fr. *campement*], the position occupied by an army or body of troops, having pitched tents or erected huts for temporary lodgings; sometimes the act of pitching tents or encamping. Also a name used for the divisions of certain secret societies, as the so-called "Knights Templar."

Encaus'tic [Gr. ἐγκαυστική, from καῦσις, a "burning"], a durable species or method of painting which was practised by the ancient Greeks, and was so called from the process of burning the picture when completed. It was not developed until the later or more perfect period of Greek art. The pictures were executed with wax colors (*ceræ*), and finished by the application of a hot iron. The effect of an encaustic picture was probably similar to that of an ordinary *tempera* or water-color painting. Both tempera and water-color pictures were polished with a wax or encaustic varnish. Encaustic painting has not been practised with much success or to much extent by the moderns.

Encaustic Tiles, a variety of tiles used for the flooring of halls, churches, and public and private buildings. They were extensively made in the Middle Ages, and were then frequently employed for the ornamentation of walls. At present figured tiles are also extensively used in making flower-boxes for window culture. Encaustic tiles are plain or ornamented. Plain tiles are white or colored, and are sometimes glazed. They are made by pressing dry clay into a mould by powerful hydraulic presses, and afterward burning them. Figured tiles are moulded from moist clay, and the figures are added to the surface before burning. These tiles constitute an excellent though expensive material for floors. Fine examples of figured tile floors are to be seen in the Capitol at Washington. Holland and Belgium had anciently famous manufactures of tiles, but at present they are chiefly made in England.

Enceinte [Fr., from *enceindre*, to "gird about," to "enclose"], in fortification, signifies the main enclosure or the (generally) continuous enclosing line of wall and parapet of a fort or fortress. It is the inner boundary of the main ditch, and, according to its "trace" or "system," upon which its contour is broken, it distinguishes the character of the work as "bastioned," "polygonal," "tenaillé," etc. (See Fortification, by Capt. O. H. Ernst, U. S. Army.)

Enchirid'ion [Gr. ἐγχειρίδιον, from ἐν, "in," and χείρ, the "hand"], in literature, a brief and useful compilation; a manual. An ethical treatise of Epictetus is termed his "Enchiridion."

Encho'rial [Gr. ἐγχώριος, from ἐν, "in," and χώρα, "country;" that is, belonging to the country, not foreign], or **Demotic Writing,** a cursive or short-hand alphabet used in ancient Egypt. It was an abbreviation of the hieratic writing, which was itself an abridged form of the true hieroglyphics. Its remains are difficult to decipher. It began to come into use about the origin of the twenty-sixth dynasty (672–525 B. C.), and was still used in 200 A. D. It contained forty-two letters and forty-eight syllabic characters. It appears on the Rosetta Stone, and was extensively employed even in public documents. Remnants of this alphabet appear in the Coptic.

Encina. See Enzina, de la (Juan).

Enck'e (Johann Franz), a German astronomer, born at Hamburg Sept. 23, 1791. He received a prize for his determination of the orbit of the comet of 1680 (called Halley's comet), and published a work entitled "The Distance of the Sun" (2 vols., 1822–24). In 1825 he was appointed director of the Royal Observatory at Berlin and secretary of the Academy of Sciences. He investigated the orbit and movements of the comet which Pons discovered in 1818, and which is now designated Encke's comet. In 1830 he began to edit the "Astronomische Jahrbücher." Died Aug. 26, 1865.

Enck'e's Com'et was observed by Pons Nov. 26, 1818. In 1819, Encke first demonstrated that the same comet had been seen as early as 1786, and several times subsequently. He also found that its period was about 1200 days (3.303 years), its successive returns being accelerated and its period shortened by a minute interval of time. It has the shortest period and the least aphelion distance of all the known comets.

Enclaves [from the Lat. *clavis*, a "key"] are small parts of one country which are entirely surrounded by another country.

En'cratites [Gr. Ἐγκρατῖται, the "self restraining," the "continent"], a name applied by the Church Fathers to a supposed Gnostic sect; though, in the opinion of most modern critics, the title belongs collectively to many Gnostics, but not to any particular sect, representing a principle, rather than a community or organization. The Encratites were dualistic, and in some instances were hardly Christian, so peculiar were their doctrines and practices. They contributed much to the spread of asceticism in the Church. Tatian, Marcion, Cassian, Saturninus, and other prominent men were reckoned as Encratites. They forbade marriage, the eating of flesh, the drinking of wine, and in some cases substituted water for wine in the Eucharist.

En'crinal Limestone, a name given by geologists to any limestone which is largely composed of the remains of crinoids, but more specifically applied to certain beds in the Helderberg and Hamilton groups in New York.

En'crinites ("stone lilies"), the popular name for crinoids, radiated animals which form an order in the class Echinodermata. The encrinites form many genera and species, nearly all of which are fossil. They abound in the palæozoic rocks, and are quite numerous in the mesozoic formations. In the present seas they are exceedingly rare, until recently only one species (*Pentacrinus caput Medusæ* of the West Indian seas) being known. The late deep-sea dredging expeditions have brought to light two or three more. *Comatula* in its early stage of existence so much resembles the encrinites that it was described as a crinoid (*Pentacrinus Europæus*), but in *Comatula* the stem is temporary, in the crinoids permanent. The stem consists of disks like button-moulds in form, set in a pile together, and in the living animal has some flexibility. It is mostly round or pentagonal, and is often finely sculptured on the articulating surfaces. Each joint of the arms is furnished with two cirri or appendages, which the animal uses in capturing its prey. The number of joints in the *Pentacrinus Briareus* is, according to Buckland, about 150,000. Immense numbers of these animals lived in the seas of the palæozoic ages. "We may judge," says Dr. Buckland, "of the degree to which the individual crinoids multiplied among the first inhabitants of the sea from the countless myriads of their petrified remains which fill so many limestone beds of the older formations."

Encum'brance. See Incumbrance.

Encyclopæ'dia, or **Cyclopædia** [Gr. ἐγκύκλιος and παιδεία (i. e. a circular or general course of education)], a compilation usually, but not always, in alphabetic arrangement, which professes to impart information, more or less complete, upon the whole circle or range of human knowledge. The most noted of the earlier cyclopædic works were—the work of Speusippus (the nephew of Plato, died B. C. 339), not now extant; the great collections of Varro, of the Elder Pliny, of Stobæus, Suidas, Isidorus, and Capella, crude summaries of the then known arts and sciences; the "Speculum Majus," in 4 parts, of Vincent de Beauvais (1264), in 3 vols.; and other similar compilations. We should note also the work of Alfarabi of Bagdad (died A. D. 950). The earliest of modern encyclopædias was that of J. H. Alsted (1630, 35 books). L. Moréri's "Grand Dictionnaire" appeared in 1673; Hofmann's "Lexicon Universale," 1677, 2 vols.; T. Corneille's "Dictionnaire des Arts," 1694, 2 vols.; and P. Bayle's "Dictionnaire Historique et Critique," 4 vols., Rotterdam, 1697. In the eighteenth century the principal works were—J. Harris's "Lexicon Technicum," 2 vols. folio, London, 1710; Ephraim Chambers's "Cyclopædia," 2 vols. folio, 1728; Zedler's "Universal Lexikon," 64 vols., Leipsic, 1732–50; the French "Encyclopédie" of the "Encyclopédists" Diderot, D'Alembert, Voltaire, Rousseau, Grimm, and Helvétius, 28 vols., 1751–72; 7 vols., 1776–80; the "Encyclopædia Britannica," 3 vols., 1771; 2d ed. in 10 vols., 1776–83; a 3d ed. in 18 vols., 1797; the "Deutsche Encyklopädie" of Köster and Roos, 1778–1804; and the "Encyclopédie Méthodique par Ordre des Matières," 1781–1832, 201 vols. In the nineteenth century the first European work was Dr. A. Rees's "Cyclopædia," 1802–19, in 45 vols. A work called the "British Encyclopædia," edited by Thomas Dobson, was published in Philadelphia 1798–1804; Dr. Brewster's "Edinburgh Encyclopædia," 18 vols., 1810–30, followed. The "Conversations-Lexikon" of F. Brockhaus, Leipsic, 1812, and of which 11 eds. have appeared, was the basis of many other cyclopædias. The "Encyclopædia Metropolitana," 1818–45, 30 vols. 4to, was a series of scientific treatises, as was also "Lardner's Cyclopædia." The "Encyclopædia Americana," 1829–33, 13 vols., and supp. vol., 1848, edited by Prof. Lieber, was based on the "Conversations-Lexikon." The "Penny Cyclopædia," 28 vols., 1833–43, subsequently rearranged in 4 divisions and 27 vols. as the "English Cyclopædia;" 8 new eds. of the "Encyclopædia Britannica," the 9th now

publishing; the "London Encyclopædia," 22 vols., 1829; and Messrs. W. & R. Chambers's "Encyclopædia," 10 vols., 1859–68, are the principal British cyclopædias of this century. In German the "Allgemeine Encyklopädie" of Ersch and Gruber, 1818 *seq.*, 160 vols. issued; Meyer's "Grosse Conversations-Lexikon," 52 vols., 1840–55; Pierer's "Universal-Lexikon," 1840–46, 34 vols.; 5th ed. 1867–71, 19 vols.—are the best cyclopædias. The French have "Encyclopédie des Gens du Monde," 1833–44, 22 vols. 8vo; "Encyclopédie Moderne," 36 vols. 8vo, 1848–57; "Encyclopédie Catholique," 18 vols. and sup.; "Dictionnaire de la Conversation," 68 vols., 1839–51; a later edition not yet complete. The later American cyclopædias have been—"The New American Cyclopædia," 16 vols., 1857–63, revised as "The American Cyclopædia," 16 vols., 1873–76; Zell's "Encyclopædia," 2 vols. large 4to, 1869–72; an abridgment, in 1 vol. 4to, 1872; "The National Encyclopædia," 8vo, 1872 *seq.*: an edition of Chambers's "Encyclopædia," printed from imported plates, 10 vols. 8vo; Schem's "German-American Encyclopædia," 1869, to be completed in 11 vols.; and "Johnson's New Universal Cyclopædia," 4 imp. 8vo vols., 1874–77. Works treating of only a single department of science, literature, or art have been called improperly *encyclopædias*. They are really dictionaries. (See also DICTIONARY and LEXICON.) L. P. BROCKETT.

Endecagon. See HENDECAGON.

Endem'ic [from the Gr. *ἐν*, "in" or "within," also "among," and *δῆμος*, a "people"]. A disease is called endemic when it is either peculiar to some locality, or, much more frequently, when it often occurs in a particular region. "Epidemics" visit a community for a time, and then disappear. "Endemics" are diseases which are very frequent in a community, and which do not disappear after running their course. Thus, cholera is epidemic in Europe and the U. S., while it is endemic along the lower Ganges.

Endemic influences are receiving profound study from students of medicine and social science. The investigations deal with climate, topography, geology, water supply, personal habits and character, moral, religious, and political conditions, and (since the origin of the germ-theory of disease) with the study of minute animal and vegetable organisms. The study of endemic influences has given rise to the new science of medical geography. (See MÜHRY, "Noso-Geographie," 2 vols.; BOUDIN, "Traité de Géographie et de Statistique Médicales, et de Maladies Endémiques," 2 vols., 1857; SIR RANALD MARTIN, "On the Influence of Tropical Climate;" the "British Army Medical Reports," annual since 1859.)

Ender'mic Meth'od, a manner of administering medicines formerly sometimes employed, by which the skin was made to absorb the remedy used. In some instances a blister was raised, and the medicine—for example, sulphate of morphia—was applied to the blistered surface. This plan, though often surprisingly effective, has been superseded by the hypodermic method, in which the medicine is introduced under the skin by a small needle-pointed syringe.

En'dicott (JOHN), colonial governor of Massachusetts, was born at Dorchester, England, in 1589. He came to America in 1628, and was chosen governor of Massachusetts colony in 1644, again in 1649, and was re-elected to the same office every year from 1650 to 1665, except in 1654. He was a bold and energetic man, a zealous Puritan, and intolerant of whatever he considered wrong. Under his administration, from 1659 to 1661, four Quakers who refused to obey the laws, which banished them from the colony, under pain of death if they returned, were executed in Boston. He died Mar. 15, 1665.

En'dive [Lat. *intu'bum* or *intybum*], (*Cicho'rium Endi'via*), a biennial herbaceous plant of the order Compositæ, cultivated in the gardens of Europe and naturalized in the East. Its blanched radical leaves are used as a salad. The varieties which have the leaves much curled are preferred. It is a native of Eastern Asia.

End'less Screw, a piece of mechanism formed by combining the screw with a cog-wheel, or by making a screw act on the threads of a female screw sunk in the edge of a wheel. The axis of the screw may be either in the plane of the wheel or at right angles to it; in the latter case it is called the American endless screw. In its mechanical principle the endless screw is a combination of the inclined plane and the lever.

End'licher (STEPHEN LADISLAUS), an eminent botanist and linguist, born at Presburg, in Hungary, June 24, 1804. He studied several Oriental languages and the natural sciences. In 1828 he became director of the Imperial Library of Vienna. He obtained in 1840 the chair of botany in the university of that city. He published several works on botany, which were splendidly illustrated. Among his numerous works are "Genera of Plants, arranged according to the Natural Order" (in Latin, 1836–40), "Iconographia Generum Plantarum" (1838), and "Rudiments of Chinese Grammar" (1845). He favored the popular cause in the revolutionary movement of 1848. Died Mar. 28, 1849.

Endocardi'tis [from *endocardium* and the termination *-itis*, denoting "inflammation"], an inflammation of the endocardium. It is generally of rheumatic character, and, though not often immediately fatal, it is a frequent cause of organic disease and deformity of the heart and its valves. It is frequently associated with pericarditis, and its occurrence is one of the results always to be feared in rheumatic fever. It is usually attended by pain or discomfort about the heart, and is detected by auscultation. It produces peculiar murmurs in the heart, the significance of which can only be appreciated by the trained physician. The disease is very intractable. Sedatives, such as hydrocyanic acid, belladonna, aconite, and digitalis, may be useful in acute stages. The alkaline treatment for rheumatism is often advantageous. Patients sometimes, though not very frequently, entirely recover.

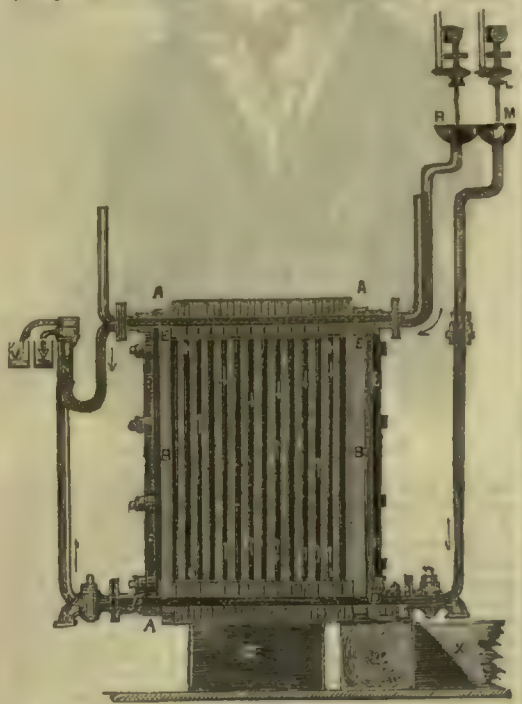
Endocar'dium [from the Gr. *ἔνδον*, "within," and *καρδία*, the "heart"], a name applied to the serous membrane lining the chambers and valves of the heart.

En'docarp [from the Gr. *ἔνδον*, "within," and *καρπός*, "fruit"], a botanical term applied to the inner coat or layer of a fruit, as the stone of the cherry and peach.

En'dochrome [from the Gr. *ἔνδον*, "within," and *χρῶμα*, "color"], the coloring-matter of plants, especially of the lower classes of plants. In the higher classes of plants it is called chlorophyll when green, and various modifications of it are believed to produce the colors of flowers, of autumn leaves, etc. Several theories have been proposed to account for these various colors, but none are quite satisfactory. The endochrome of the lowest plants has been pronounced by some chemists to be identical with chlorophyll, except when stained by the presence of iron, etc., as in diatoms.

En'dogens, or Endog'enous Plants [from the Gr. *ἔνδον*, "within," and *γένω*, to "be born," to "grow"], one of the primary classes of plants, are sometimes called **Monocotyledonous.** All flowering or phænogamous plants are divided into two classes, the endogens and the exogens. The former are so called because their stems grow by additions to the inside, so that the outer part is the oldest and hardest. The stems present no manifest distinction into bark, wood, and pith, but the woody fibre and vessels are in bundles which are irregularly imbedded in the cellular tissue. They have no true medullary rays, nor proper bark, nor concentric annual rings. The leaves are mostly parallel-veined, and sheathing at the base. The stems of most endogens produce terminal buds, but no lateral buds, and therefore are unbranched. The stem generally ceases to increase in thickness at an early stage of its growth, long before it attains its full height. In many of the grasses the stem is hollow or fistular. The endogens of temperate and cold climates are mostly small herbaceous plants, as grasses, lilies, and rushes; but in warm climates occur numerous endogenous trees, as the palm and pandanus or screw-pine. The embryo of all endogens has a single cotyledon, and the plumule has alternate leaves. Most endogens have the parts of the flower in threes, and the leaves in the vast majority are parallel-veined.

En'dor, an ancient village of Palestine, on the northern declivity of Little Mount Hermon, 18 miles S. E. of Acre.



Endorse [from the Lat. *in*, "on," and *dor'sum*, "the back"], in heraldry, the smallest diminutive of the pale; an ordinary containing the fourth part of a pale.

Endorse, or **Indorse,** to write on the back of a promissory note or other written instrument; to sanction; to become responsible for (a bill or note). The party who endorses is called the *endorser*. Each endorser is liable for the payment of a bill or note in case the drawee or acceptor fails to pay, as the case may be, provided that protest is legally made in time.

En'dosmose, or **Endosmo'sis** [from the Gr. *ἔνδον*, "within," and *ὠθέω*, to "impel"], and **Exosmose,** together called **Liquid Diffusion, Osmose** or **Osmotic Action,** are properties of animal and vegetable membranes first observed by Dutrochet (*Ann. Chim. Phys.*, xxxvii. 191), and subsequently investigated very fully by Graham. If two different liquids or gases which are capable of mixing with each other, as water and alcohol, are separated from each other by such a membrane as paper, caoutchouc, or a bladder, the one liquid being suspended in a bladder in the other, the liquid in the bladder will pass through the bladder into the other (exosmose), or the liquid without will pass into the bladder (endosmose), or both endosmose and exosmose will take place at the same time; and in this case the

current continues until there is an equal proportion of both liquids on either side of the bladder. These phenomena are due to the attraction which the two liquids have for each other and for the diaphragm separating them. These phenomena are essential to organic life, and perform important parts in many physiological acts. Advantage is taken of them in dialysis and many other operations of the chemist.

Diffusion is applied in France and Germany to the extraction of the saccharine juice from beets and to the separation of alkaline salts from beet molasses. For the latter purpose the "osmogene" was devised by Dubrunfaut. (*Comptes Rendus*, lxv. 692. See also Walkhoff's "Rüben-

Dubrunfaut's Osmogene.

zucker-fabrikant.") The osmogene consists of a box (B B) containing sheets of parchment paper (H H) held in a vertical position by wooden frames with rubber padding (A A). A stream of water (M V) flows through the box, filling half the spaces between the diaphragms. At the same time a stream of molasses (R V') flows through, filling the alternate spaces. The alkaline salts diffuse through the parchment, purifying the molasses to such an extent that the process is a profitable one for the manufacturer.

Endow'ment, the act of appropriating a fund for the support of a charitable institution, a professorship, or a college; also the fund or revenue devoted to such a purpose or permanently appropriated to any object; sometimes a gift of nature, an innate faculty or quality.

Endrödi, a village of Hungary, in the county of Bekes-Csanad, on the river Körös, 90 miles E. S. E. of Pesth. Pop. in 1869, 8714.

Endym'ion [Gr. *Ἐνδυμίων*], in the Greek mythology, a beautiful youth beloved by Diana (Selene), who cast him into an everlasting sleep. One tradition represents him as a son of Zeus (Jupiter), who gave him immortality and perpetual sleep. Some persons suppose that Endymion is a personification of the sun or of the plunge of the setting sun into the sea.

En'ema [from the Gr. *ἐνίημι*, to "send in"], a liquid substance thrown into the rectum by injection, either as medicine or nourishment.

En'emy [from the Lat. *in*, negative, and *amī'cus*, a "friend;" Fr. *ennemi;* Ger. *Feind*], one hostile to another; a foe, an adversary, an antagonist; applicable to an individual or a nation. Also one who dislikes any individual or cause; a hostile army or force. In international law, the enemy is one who has publicly declared war against us, or against whom we have made such a declaration. This declaration must be made by a duly organized state or kingdom, for such a declaration by any turbulent body of men is not sufficient. Hostilities having been formally declared, every subject or citizen of the hostile nations becomes an enemy of the opposing state, and all intercourse or communication between the citizens of one hostile state and those of the other is unlawful. An enemy cannot, as a general rule, enter into any contract which can be enforced in the courts of law; except, for example, when a state permits expressly its own citizens to trade with the enemy; and perhaps a contract for necessaries or for money to enable the individual to get home might be enforced. An alien enemy cannot, in general, sue during the war a citizen of the U. S., either in the courts of the U. S. or those of the several States. The word *enemy*, in a still more extended sense, includes any of the subjects or citizens of a state in amity with the U. S. who have commenced, or who have made preparations for commencing, hostilities against the U. S.; and also the citizens or subjects of a state in amity with the U. S. who are in the service of a state at war with them. The Latins had a particular term (*hostis*) to denote a public enemy, and distinguished from him a private enemy by the term *inimī'cus*. In our language we have but one word for these two classes of persons. (See Contraband, Embargo, Piracy, and War.)

En'ergy [Gr. *ἐνέργεια*, from *ἐν*, "within," and *ἔργον*, "work"], in physics, the capability of effecting physical changes; that is, of doing work or overcoming resistances. It is called *actual energy* in reference to the work it is doing, and *potential energy* in reference to that which it is capable of doing, but has not yet done. A bent spring possesses *potential energy;* the same spring set free exerts *actual energy*. Energy is called *visible* when motion is directly perceptible in the moving body; it is called *molecular* energy when the motion occurs among the particles of a substance, and is not directly perceptible. Visible energy is called *kinetic* when it is due to visible motion; the kinetic energy of a moving body is equal to the weight in pounds multiplied by the square of the velocity, and divided by twice the acceleration due to gravity. When a body moves to the highest point in its course, its kinetic energy is exhausted, or rather converted into *potential* energy, which is due entirely to advantage of position. As kinetic energy decreases, potential energy increases, and the sum of the two in any moving body is always the same. Molecular energy is due to heat, actinism, chemism, electricity, etc. Various machines, such as the steam-engine, the telegraph apparatus, etc., depend for their action upon the conversion of molecular into kinetic energy. (See Correlation of Forces.)

Enfantin (Barthélemi Prosper), a French socialist and leader of the Saint-Simonians, was born in Paris Feb. 8, 1796. He became in 1825 a disciple of Saint-Simon, after whose death he and Amand Bazard were the chief priests of the sect. They formed in 1830 an association of Saint-Simonians, who had their property in common, but they soon disagreed and ceased to co-operate. Enfantin assumed the name of the "Living Law and the Messiah." He wrote several socialist works and advocated "free love." In 1832 he was imprisoned on a charge of corrupting public morals. Died May 31, 1864.

En'field, a town of England, in Middlesex, on the London and Cambridge Railway, 10 miles N. of London. Here is a large manufactory of small-arms belonging to the government. Pop. 16,053.

Enfield, a post-township of Hartford co., Conn. It contains a settlement of Shakers, and has important manufactures. Pop. 6322.

Enfield, a post-township of White co., Ill., at the crossing of the Springfield and Illinois South-eastern and the St. Louis and South-eastern R. Rs. Pop. 2426.

Enfield, a post-township of Penobscot co., Me., on the European and North American R. R., 35 miles from Bangor. Pop. 545.

Enfield, a post-village and township of Hampshire co., Mass. It has important manufactures. It is on Swift River and on the Athol and Enfield R. R. Pop. 1023.

Enfield, a post-township of Grafton co., N. H., 42 miles N. W. of Concord, is on the Northern R. R. The United Society of Shakers occupy a portion of the town; they manufacture brooms, tubs, and pails, and raise garden-seeds. The three lakes in the town and the beautiful scenery around them make this one of the most delightful summer resorts in New Hampshire. There are two hotels, two woollen-mills, five churches, and one monthly medical journal. It has also manufactures of furniture, flannels, leather, lumber, knit goods, carriages, etc. Pop. 1662.

Eli G. Jones, M. D., Ed. "N. E. E. Medical Journal."

Enfield, a post-township of Tompkins co., N. Y. Enfield Falls, 230 feet high, are on Ten-mile Creek, and are very beautiful. Pop. 1693.

Enfield, a post-village of Halifax co., N. C., is on the Wilmington and Weldon R. R., 18 miles from Weldon and 144 from Wilmington. It contains several steam saw-mills

and one steam grist-mill. It has one newspaper. There is a large wine-manufactory in the vicinity. The principal export is cotton; it ships annually 5000 bales of cotton, 15,000,000 feet of lumber, 500,000 staves, 3000 bushels of early peaches, besides shingles, wine, and brick. A gold-mine is worked in the neighborhood. Pop. about 500.

DANIEL BOND, ED. "TIMES."

Enfield (WILLIAM), LL.D., an English dissenter and writer, born at Sudbury in 1741. He preached in the Unitarian churches of Liverpool, Warrington, and Norwich, and published several volumes of sermons and a "Preacher's Directory" which is highly commended. Amongst his other works is a "History of Philosophy" (1791), abridged from Brucker's history. Died Nov. 3, 1797.

Enfield Rifle-Musket, a variety of small-arms manufactured at Enfield, England, at the royal small-arms factories. During the late civil war the U. S. government and the Confederates each purchased large quantities of these and other European arms, on account of the difficulty of supplying the large numbers of troops with the necessary weapons. The Enfield rifle, though a very serviceable weapon, much better than the Belgian and Austrian arms then imported, was in almost every respect inferior to the old Springfield (U. S.) rifle-musket, which it much resembles. All these weapons have now given place to various breech-loading arms.

Enfilade [Fr.], a discharge of musketry or artillery made in a direction parallel to the length of a line of troops or of a line of rampart, so that the shot rakes the whole line. A trench or parapet is said to be *enfiladed* when guns are so placed that the shot can be fired into it in a direction coincident with its length.

Engadine, or **Engadin,** an extensive valley in Switzerland, canton of Grisons, is about 45 miles long, and has an average width of 1½ miles. The noble Bernina Mountains separate this valley from the Valtelline. It is the upper part of the valley of the river Inn, which runs along it in a north-east direction between two chains of the Alps. The highest part of the valley is 5900 feet above the level of the sea. The climate is very cold, and snow and frost occur even in July. The valley is divided into the Upper and Lower Engadine. There are several glaciers and a number of valuable mineral springs. The inhabitants number about 12,000, and speak a peculiar Romanic dialect, called Ladin. The people are mostly Protestants. The valley is very beautiful, and affords much timber and pasturage. The Lower Engadine is well cultivated, but less beautiful than the upper valley. The people are a pious, simple class of peasantry. The young men are known throughout Europe as good confectioners and coffee-house keepers. They usually amass a competence, and return to enjoy their small fortunes in their native valley. The government is a pure democracy. The noble Cembra pines which adorn this valley are of great value.

Eng ("right") and **Chang** ("left"), the Siamese Twins. They were born at Bangesau, Siam, April 15, 1811, of a Chinese father and a Chino-Siamese mother, and brought to the U. S. in 1829. Since that time they have been on exhibition in America and Europe a number of times, and died, after having lived, as Eng and Chang Bunker, about twenty years in the neighborhood of Mount Airy, N. C., in Jan., 1874, the death of Chang preceding that of Eng a few hours. They differed in appearance, character, and strength more than average twins, performed their physical functions separately, and were addicted to different habits, Chang being intemperate and irritable, Eng sober and patient. Both were married and had large families of children, a number of whom died young, but none exhibited any malformation. Chang received a paralytic stroke in Aug., 1870. He died unexpectedly while his brother was asleep, after having been affected with an inflammatory disease of the respiratory organs. Eng died a few hours afterwards, probably chiefly from the influence of the nervous shock on learning the sudden death of his brother. They are the best known of the "double monsters" on record, none others of whom ever lived to the advanced age of sixty-three. The "Hungarian Sisters," Judith and Helena, who were born in 1701, and connected at their sacral regions, lived up to twenty-one years of age, and the "Two-headed Nightingale," two mulatto girls of North Carolina, born in 1851.

The connection of the Siamese Twins took place in their epigastric regions, between the navel, which was common to both, and the ensiform processes, which were bent out in a forward direction and met very closely, held together by a ligamentous apparatus. The connecting band was a few inches long, after having elongated a little during the long life of the twins, and eight inches in circumference (two and a half in diameter). It was covered with skin, which in the median line had a narrow zone with common sensitiveness. Inside the skin there was normal subcutaneous and muscular tissue, portions of the muscles of one crossing those of the other. The interior was occupied by the prolongation of the peritoneum in such a manner that at the post-mortem examination a hand introduced into the abdomen of Chang entered two pouches reaching into Eng, and a hand introduced into the abdominal cavity of Eng entered one pouch (lying between the two of Chang's) which was long enough to be extended into the abdomen of Chang. The livers of the twins were located in close proximity to the connecting band, and connected with each other by small blood-vessels, which were lined with a thin layer of genuine liver tissue. Thus, the question whether a separation of the twins by surgical means would have been possible, must be answered negatively. The severing knife would have injured the peritoneum of both brothers, and resulted in a very dangerous (although perhaps not necessarily fatal) inflammation. The greatest danger would have resulted, however, from the lesion of the short connecting blood-vessels, particularly the vein, and the accompanying liver tissue. Two separations, by surgical interference, of "double monsters" are on record: one is reported by König in 1689, one by Boehm in 1866. (*Virchow's Archiv.*) The latter operated on his own twin daughters in 1861; one died after three days, the other was alive in 1866, at the age of five years. In both cases the connection of the twins took place in the exact place where the Siamese Twins were attached to each other, but the connection was confined to the skin and subcutaneous tissue only.

A. JACOBI.

Eng and Chang (the Siamese Twins).

Engano, an island of the Malay Archipelago, is near the S. W. coast of Sumatra. It is over 30 miles in circuit, and is rather high and well wooded. Area, 400 square miles. The people are of Malay race, and are independent. The island has a good harbor, but is mostly surrounded by coral-reefs. Lat. 5° 21′ S., lon. 102° 20′ E.

En-gedi [Heb. *Eyn Gedi*, the "kid's fountain:" the modern *Ain Jidy* of the Arabs], a town several times mentioned in the Bible, and also called *Hazezon-tamar*, alluding to its palm trees, which have now disappeared. It stood on the W. side of the Dead Sea, at a point about equally distant from its N. and S. extremities. Here are found some ruins of the old town, which stood in a very fertile spot near the fine fountain which gave it a name. There are numerous caves in the vicinity. These served as hiding-places for King David and his followers in the days of their outlawry during the reign of Saul.

Eng'el (ERNST), a very prominent German statistician, born in 1821, became in 1860 director of the statistical bureau in Berlin, and presided in 1863 in the International Statistical Congress in Berlin. He published the "Zeitschrift des statistischen Bureau" (since 1860), the "Jahrbuch für die amtliche Statistik des Preussischen Staates" (since 1863), and "Preussische Statistik" (since 1866).

Engel (JOHANN JAKOB), a German author of much merit, was born at Parchim Sept. 11, 1741. He became professor of belles lettres in Berlin in 1776. Among his works are "Ideen zu einer Mimie" (2 vols., 1785), and "Lorenz Stark" (1795), a romance which was very popular. His

works are characterized by a refined taste and great elegance of diction. Died June 28, 1802.

Engel (Joseph), a German anatomist, born in 1816, became professor of descriptive anatomy at the University of Zurich in 1844, professor of pathological anatomy in Prague in 1849, and of descriptive anatomy at the Joseph Academy in Vienna in 1854. He published, among other works, "Specielle pathologische Anatomie" (1856), "Das Knochengerüst des Menschlichen Antlitzes" (1850), and "Compendium der topographischen Anatomie" (1859).

Eng'elberg, a village in a valley of the same name, in the canton of Unterwalden, Switzerland, at the foot of Mount Titlis. It is famous for its school, which is connected with a stately Benedictine abbey, *Mons Angelorum*, founded by Pope Calixtus II. in 1120, and rebuilt in 1729. It has a good old library and some valuable paintings. Here is also a famous cheese-cellar of great extent.

Engelbert, a voluminous old Benedictine author, was abbot of Admont in Styria, and died in 1331. He was of noble birth. Of his numerous works the most important was a Roman history, "De ortu, progressu et fine imperii Romani," published in 1553 and 1603. Several theological tractates of his production have been published by Pez, with a biography and a full list of his works.

Engelbert, Saint, a son of Engelbert, count of Berg-Geldern, was born in 1185. He became in 1215 elector of the empire and archbishop of Cologne, having when twenty-two years old declined the bishopric of Münster. He paid off the debt of the electorate, enlarged its territories, and reformed its administration. When the emperor Frederick II. went to Italy, Engelbert was the principal regent in Germany. He reformed the corrupt clergy, checked the power of the nobles, and zealously advanced that of the Church. His energy and rigor made many enemies, and he was murdered by his own nephew Nov. 7, 1225. The murderer, Count von Isenburg, was broken on the wheel, and his accomplices, the bishops of Osnabrück and Münster received excommunication. Saint Engelbert is one of the characteristic figures of German mediæval history, recalling Saints Dunstan and Thomas à Becket, but he seems to have possessed more zeal for the purity of the Church than they showed, and an energy equal to theirs in extending its power. His life was written by Cæsar of Heisterbach, and in recent times by Ficker.

Engelbrecht (Johann), a German enthusiast, born at Brunswick in 1599. He was a tailor's son, and worked at his father's trade until his health failed. He was liable to cataleptic attacks, during which he went for many days without food or drink. In 1622 he set himself up for a prophet, in all sincerity regarding himself as a divinely-inspired teacher. His writings have been in part translated into English. Though he was quite unlettered, some of Engelbrecht's books, like his addresses, display considerable power and an insight into spiritual things. After suffering imprisonment and enduring much obloquy, he retired from public life and died in 1642.

Eng'elmann (George), M. D., a German botanist and physician, born at Frankfort-on-the-Main Feb. 2, 1809, was educated at Frankfort, Berlin, and Heidelberg, removed to the U. S. in 1832, and settled at St. Louis in 1835. He founded there a journal called "Das Westland." He is especially eminent for his researches in the Cactaceæ, the dodders, the euphorbias, junci, conifers, and other difficult departments of botany. He has published various monographs on botany and meteorology.

Eng'elstöft (Christian Thorning), a Danish theologian, born in 1805, became in 1845 professor of theology at the University of Copenhagen, and in 1851 bishop of Fühnen. He wrote, among other works, a "Manual of Church History" (1845).

Enghien, a town of Belgium, province of Hainaut, about 20 miles S. W. of Brussels, with which it is connected by railway. It has a superb château of the Aremberg family, and manufactures of cotton and linen fabrics. The family of Bourbon-Condé derived from it the title of duke. Pop. in 1866, 3852. The great Condé was styled in his youth Duc d'Enghien.

Enghien, d' (Louis Antoine Henri de Bourbon), Duc, a French prince, born at Chantilly Aug. 2, 1772, was the eldest son of the duke of Bourbon. He became an *émigré* in 1789, and joined in 1792 the army of the prince of Condé, who was his grandfather. He fought against the French republic until 1799. In 1804 he married the princess Charlotte of Rohan-Rochefort, and became a resident of Ettenheim in Baden. Here he was seized by the order of Bonaparte, carried to Vincennes, tried by a military court, and shot Mar. 21, 1804, on the pretext that he was an accomplice of Cadoudal in a conspiracy against Bonaparte. This act excited great indignation, as it is generally believed that D'Enghien was not guilty.

En'gine [probably from the Latin *ingenium*, "natural capacity," "invention"], a name given to a variety of mechanical contrivances designed to apply the forces of nature in performing useful work. In a general sense, the word is often applied to any powerful machine, but its use in industry is restricted to prime movers. Here also a distinction is to be observed. Prime movers of great simplicity, like windmills and water-wheels, are not called engines. Something implying the exercise of ingenuity (*ingenium*) in the combination of parts and the adaptation of means to ends is necessary to entitle a machine to be ranked in this class.

The forces which engines are employed to apply and utilize are principally heat, gravity, and electricity. Those in which the efficient force is heat, called in general thermodynamic engines, occupy the first rank as it respects their industrial value; and among these the class of engines in which steam is the vehicle employed to utilize the heat are the most important of all. The varieties of steam-engines are almost as numerous as the uses to which they are applied; but in most the elastic force of the steam is employed to impart, by direct pressure, a reciprocating rectilinear motion to a piston within a cylinder, this motion being usually converted into a rotary motion by means of a crank. Such is the principle of all the large stationary engines used to drive the machinery of factories, foundries, etc., and generally of those employed to propel vessels on inland waters or on the ocean, or to drag trains upon railways. Such also is the principle of most of the steam-engines used in the minor industries, and of the portable engines (called by the French *locomobiles*) employed in agriculture and for miscellaneous purposes.

The real or supposed disadvantages attendant on the use of crank motion have led many inventors to seek a form of construction for the engine in which rotary motion should be produced by the direct action of steam. Hence there has sprung up a very numerous tribe of "rotary engines;" none of which, however, have secured a very general acceptance. (See Rotary Steam-Engine.) A plan of marine engine has also been proposed, and perhaps constructed, in which the rotary and reciprocating motions are in a certain sense combined, the piston being a plane passing through the axis of the cylinder, around which (axis) it vibrates through a considerable arc. The object in this case is to economize space, and to keep the heavy parts of the engine as low down in the ship as possible. Finally, Bishop's disk engine, another marine engine intended for driving propeller screws, employs as a piston a disk, which, moving in what may be called an equatorial spherical sector upon a ball-and-socket joint at the centre of the sphere, gives to the polar axis a motion of nutation by which the crank is driven. This construction is said to have been very successful.

The first application of steam to produce a useful effect was made by Captain Thomas Savery, a British engineer, in a contrivance for the drainage of mines or the elevation of water generally, of which he exhibited a model in 1669 to the Royal Society of London—a contrivance usually but improperly called Savery's *engine*. This consisted of a vessel, or pair of vessels, of metal, ellipsoidal in form, called receivers, connected at the bottom by a tube having a valve opening upward with the water to be raised, and having a pipe descending to the bottom of the receiver within, but furnished with a stop-cock at top, which communicates upward with the level at which the discharge is to take place. In this apparatus, the cock being open, the air is first expelled by steam introduced from a boiler; the cock being then closed, the steam is condensed by means of cold water applied to the surface of the receiver; into the vacuum formed by this condensation the water then enters by force of atmospheric pressure, lifting the valve; the receiver being full, the cock is once more opened, the valve closing spontaneously, and steam is introduced at the highest point of the vessel, pressing on the surface of the water, and driving it upward through the discharge-pipe. Owing to the small conducting power of fluids for heat downward, the temperature of the water is very little raised during this operation, and that only near the surface. This contrivance, though very wasteful of heat, came into quite general use in England. One of the first uses to which the inventor himself applied it was for the raising of water to be used by its fall to turn a mill-wheel; and it is said (*Encycl. Brit.*, art. "Steam-Engine") that several engines of this kind were erected at Manchester to impel the machinery of some of the earliest cotton-mills and manufactories of that district. It should be here observed that the marquis of Worcester, in his "Century of Inventions," published in 1663, described a machine identical in principle with that of Savery, which he asserts

that he actually constructed and operated successfully; but as no evidence of this remains but his own record, the statement is to be received with some hesitation.

In 1690, Denis Papin, a French physicist (at that time, however, curator of the Royal Society of London), devised a project—or rather, it may be said, suggested the possibility—of an engine in which the efficient power should be the pressure of the atmosphere; this to be brought into play by creating a vacuum beneath a piston in a cylinder by the explosion of gunpowder or by the condensation of steam. Dr. Papin, however, did not follow out his idea. It was taken up by two common mechanics, Newcomen and Cawley of Dartford, who some years later (the precise date of the invention is not preserved) produced a machine having a real industrial value, which, under the name of Newcomen's engine, continued to be used, chiefly in the drainage of mines, for nearly a century. In this engine a vacuum was produced beneath a piston in an upright open cylinder by first filling the cylinder with steam, and then condensing the steam by the application of cold water to the exterior. The downward pressure of the atmosphere—about fifteen pounds to the square inch, or a ton to the square foot—then caused the piston to descend, dragging after it the working-beam of the engine or (in raising water) the handle of the pump. Two important improvements were made soon after the introduction of this engine. The first was the condensation of the steam by means of a jet of cold water thrown into the interior of the cylinder, instead of applying water to the surface. The discovery of the superior efficacy of this method was the result of an accidental leakage, through the piston, of the cold water always kept on top to prevent the entrance of air, in consequence of the imperfect fitting of the piston to the cylinder. The sudden descent of the piston on the occurrence of a free influx of water thus occasioned suggested an arrangement for the purposed introduction of the jet at the proper instant, whereby the movements of the engine were greatly accelerated. The second improvement consisted in attaching rods to the working-beam, so connected with the cocks by which the steam and condensation water were alternately admitted to the cylinder as to cause those cocks to be opened and closed at the proper moments by the action of the machine itself. The engine thus became automatic; and this most valuable addition to its capabilities of usefulness is said to have been made by a boy named Humphrey Potter, employed to tend the engine, and charged with the monotonous duty of opening and closing these cocks by hand. Observing that the opening of one of the cocks was necessary at the beginning of the stroke, and that of the other at the end, also that when one was opened the other must be closed, he attached strings to the handles of the cocks, and so connected them with the beam as to produce the desired effects in their proper order. In planning and successfully executing this contrivance the youthful inventor had not particularly in view the benefit to the world it was capable of yielding, but only his own personal relief from an irksome task. He designed, therefore, to keep it a secret, in order that he might enjoy the liberty it secured him. But the very excellence of his invention betrayed him. The engine provided with his attachments immediately began to work with a uniformity and regularity unknown before, exciting the curiosity of the attendants to discover the cause; so that the secret was brought to light. The name given to Newcomen's engine was not "the steam-engine," but "the atmospheric fire-engine."

In 1725 appears to have been produced the first engine (for the machine of Savery was not properly an engine) in which the direct pressure of steam was employed as a motive-power. This was invented by one Jacob Leupold, whose contrivance embraced a piston in an open cylinder, like Newcomen's, but employed high-pressure steam, not only to balance the pressure of the atmosphere, but to drive at the same time the piston of a force-pump elevating a column of water.

This was the state of things in regard to thermo-dynamic engines when in 1765 the attention of James Watt, a mathematical instrument maker of Glasgow, was called to the subject, in consequence of his having been called upon to make some repairs upon a model Newcomen engine used to illustrate the physical lectures of the university of that city. In the hands of Watt this contrivance completely changed its character, and became, in the proper sense of the word, a steam-engine. (For the further history of this most important of the mechanical aids to the industrial progress of the world, for a description of the variety of forms which have been given to it, and of the accessory apparatus by which its efficiency has been improved, and for an account of the physical and mathematical theories of its action, we must refer the reader to the proper heads, STEAM-ENGINE and HEAT.)

Thermo-dynamic engines have been proposed, in which ammoniacal gas or the vapor of ether or that of some other volatile liquid should be made the vehicle of the thermal force. These have been in some instances actually tested, but they have never gained a general acceptance. The argument urged in their favor has been of course economy, but the basis of this economical argument has been greatly narrowed by the recognition of the doctrine of the conservation of force as one of the fundamental truths of physical science. There remain, nevertheless, certain questions relative to this point still open, which will be found briefly discussed in the article HEAT. Other forms of thermo-dynamic engines, which have secured to themselves a place among the aids to industry, are those which employ as a direct or indirect source of motive-power the explosive force of combustible gases when inflamed in mixture with atmospheric air, and those in which the elastic force of heated air itself is used to drive a piston. (For descriptions and theories of these, see HEAT, HOT-AIR ENGINE, and INFLAMMABLE-GAS ENGINE.)

The attempt to make electricity subservient as a motive-power to the uses of the arts has been many times made, but never with a high degree of success. There is no difficulty whatever about the undertaking, considering it merely as a mechanical problem. From the point of view of economy, however, such attempts will always be failures, unless there should be discovered some source of electro-motive force less expensive than any now known. (For information on this subject, see ELECTRO-DYNAMIC ENGINES.)

Hydro-dynamic engines are those in which water is employed not simply to produce motion by its own gravity, as in falling upon an overshot or breast wheel, or by its moment, as in driving an undershot or flutter wheel, but by the hydrostatic pressure of a natural head, or of what may be called an artificial head, produced by confining a large volume of water in a strong cylinder, and compressing it by means of a heavily loaded piston in the cylinder. Such engines are usually of small dimensions, but work under a very high pressure—a pressure sometimes of three or four hundred atmospheres. They were originally introduced by Sir William Armstrong to control the heavy cranes and other lifting machinery used in foundries, and were first publicly exhibited by him in the great International Exposition of 1851, held in London. In the management of the ponderous "converters" used in Bessemer steel-works they may be said to be indispensable. (See on this subject the article HYDRO-DYNAMIC ENGINES.)

F. A. P. BARNARD.

Engineering. "The engineer is he who, by art and science, makes the mechanical properties of matter serve the ends of man. In the widest sense, almost every man is more or less an engineer. The first man who bridged a torrent with a fallen tree had in him something of the engineer; the first man who dug a new channel for a brook, the first man who cleared a pathway in the forest, had in him something of the engineer; but the title of engineer is more properly restricted to those who make the useful application of mechanical science their peculiar study and profession." *

Hence, engineering is the art and science by which "the mechanical properties of matter are made to serve the ends of man," or, as otherwise defined, it is "the useful application of mechanical science" to those ends.

The branches of science which are applicable to the engineer, says the same eminent authority, "fall under the general head of *mechanics;* but they are distinct in method and application (though not in principle) from astronomical mechanics, which treats of the motion of the stars, and from those parts of physical mechanics which relate to such subjects as the transmission of sound and light. They are also so far to be kept distinct from *pure* or *abstract* mechanics that, in treating specially of mechanics as applied to engineering, certain fundamental principles are to be taken for granted, the demonstration of which forms part of the course of natural philosophy. To that course also must be left all mechanical problems which are interesting in a scientific point of view only, and not practically useful.

"The objects to which the science of the engineer relates are divided under two heads—viz., *Structures* and *Machines.*

"Strictly speaking, all machines are structures, though all structures are not machines; but it is convenient to limit the term *structures* to those combinations of solid materials whose parts are not intended to have relative motion, and which are thus to be distinguished from *machines*, whose parts are intended to have relative motion and to perform work.

"The theory of structures is founded on the principle of statics, or the science of equilibrium. It is divided into two parts, relating respectively to the two requisites of a struc-

* The late W. J. Macquorn Rankine on "The Science of the Engineer."

ture, stability and strength—stability being the power of resisting forces tending to overthrow the structure, or to derange the parts of which it is made from their proper relative positions; and strength, the power of resisting forces tending to alter the figures of those parts or to break them in pieces.

"For example, in a bridge, stability requires certain relations to exist between the distribution of the load, the figure of the arch, and the dimensions of the abutments, in order to prevent the dislocation of the arch-stones or the overthrow of the abutments; and strength requires the arch to be of a thickness sufficient to resist the tendency to crush it.

"In applying the principles of stability and strength to structures, regard must be had to the special properties of the materials employed, whether earth, stone, bricks, cement, timber, iron or other metals, as well as to the kind of workmanship to which each material is subjected, and the forms in which it is used.

"The end to be aimed at in every scientifically designed structure is to adjust exactly the position, form, and size of the whole, and of each part, to the forces which it has to sustain. The more nearly this end is attained, the better will the structure be, not only in efficiency, durability, and economy, but also in beauty. This, independently of ornament, is the fundamental principle of beauty in architecture as well as in engineering.

"The theory of machines is founded on the principles of cinematics, or the science of motion considered in itself, and on those of dynamatics, or the science of the relations between motion and force.

"Pure mechanism is the name which has been given to the cinematical part of the theory of machines, or that which takes into consideration their action in transmitting and modifying motion only, without regard to the force which is at the same time transmitted. As examples of its application may be cited parallel motion, the arrangement and proportioning of wheels, and the correct shaping of their teeth. The science of pure mechanism has of late been brought to a very complete state, and reduced entirely to the consequences of one general principle.

"The dynamical part of the theory of machines considers them as transmitting at once both motion and force, or performing *work*. It treats of the resistances, whether from solids or fluids, which impede the action of machines, the means of regulating that action, and the nature of the sources of motive-power, whether animal strength, the gravitation of water, the currents of the air, or the mechanical action of heat. The entire theory of the work of machines is founded on one principle, that of the *conservation of energy*.

"Machines have further to be considered with reference to their strength, or capacity for sustaining without injury the forces which they transmit.

"The term *civil engineering* is applied to a wide and somewhat indefinite range of subjects, but it may be defined as embracing those applications of mechanics, and of the arts of construction generally, which belong to lines of transport for goods and passengers, whether roads, railways, canals, or navigable rivers; to works for the conveyance of water, whether for drainage or water-supply; to harbors and works for the protection of the coast. All these kinds of works are combinations of structures and machines; they comprise *structures*—in earthwork, as cuttings, embankments, and reservoirs; in masonry, timber, and iron, as bridges, viaducts, aqueducts, locks, basins, piers, and breakwaters; they comprise *machines*—such as carriages and locomotive engines, lock-gates, sluices, and valves, pumping steam-engines, and dredging-machines. Their principles, therefore, consist to a great extent of the general principles of construction and machinery, combined and adapted to suit the circumstances of each kind of work.

"But civil engineering has besides some principles peculiar to itself. It involves the art of laying out lines of transport and selecting the sites for works in the best manner possible with reference to the features of the country, so as to secure economy in execution and working. Hydraulic engineering involves the laws of rainfall and of the supply and the flow of streams; and the engineering of coast-works requires a knowledge of the action of the waves and tides."

In addition to the above, geology and mineralogy, chemistry in so far as it relates to the treatment of metals and of building materials, botany and vegetable physiology with special reference to timber trees, are indicated as departments of science which every engineer would do well to study.

An art or science which makes the mechanical properties of matter serve the ends of man embraces also military engineering, of which the object is the application of these properties to the operations of war. In a technical sense, military engineering is more restricted, and embraces fortification, whether permanent or temporary, and its auxiliaries, such as floating obstructions and torpedoes for harbor defence; the works of attack or defence of fortresses, or, in other words, sieges, both active and passive; the construction and the laying of military bridges; reconnaissances and surveys for military purposes, including the operations of armies in the field; the works of field fortification, whether lines for the holding of extensive areas of the theatre of war, or those transient works (*fortifications improvisées*) by which troops are protected in line of battle; and in general, if we make the distinction which has already been made in another place, it embraces the *constructions* for military purposes as distinguished from warlike *machines*, though perhaps the line is not so sharply drawn as in civil engineering. Military engineering, among all the great military powers of the world at the present day, is made the special subject of study, as distinct from other branches of the art of war; but the exercise of its functions is committed to special military organizations called "corps of engineers," or its equivalent. (For more particular information on this subject consult "The Royal Engineer," by Sir Francis B. Head; Heydt, "Recherches sur l'organisation du Corps du Génie en Europe;" and Allent, "Histoire du Corps du Génie.")

In a more general sense, military engineering embraces also artillery, gunnery, military pyrotechny, transportation, including vehicles, railways (especially their repair and preservation, and the renewal of destroyed bridges in war), and in general all those branches of civil engineering which are involved in the foregoing.

Another great department of engineering science is that which relates to the extraction of metallic ores, coal, and other valuable minerals from the earth. Its general principles are those of civil engineering, but the circumstances under which they are applied impose the necessity of materially modifying the methods. Mining engineering may be said, then, to embrace the methods of underground surveys, which in many respects differ from those on the surface; the proper modes of reconnoitering, reaching, and attacking mineral deposits; drifting galleries, sinking shafts, and timbering and walling the same; the ways and means of interior transportation; methods of hoisting in shafts or slopes; the construction of engines for lifting minerals or miners, and of pumps for the extraction of mine water; and, finally, the proper ventilation of underground works. It describes the miner's methods of attack in detail, the dangers which he has to encounter, and his means of precaution and defence; and further treats of the mechanical preparation or milling of ores, and of those constructions in the open air which are part of the plant of a mine, but which are operations referable to civil engineering and building.

(For more particular information in regard to special branches of engineering science, see Aqueduct, Artillery, Breakwater, Bridge, Dock, Dynamics, Fortification, Gunnery, Harbor, Hydro-dynamics, Jetty, Lighthouse, Machinery, Mensuration, Mining, Navigation (Inland), Ocean Navigation, Railway, Road, Shipbuilding, Thermo-dynamics, Tunnel.)

J. G. Barnard, *U. S. Army.*

Engineers, Corps of. Among all modern nations assuming to be military powers, the engineering service is organized into separate corps (see Engineering), and for the training of *élèves* for service in them, special military schools are generally provided. (For information as to the organization of these corps see Heydt, "Recherches sur l'organisation du Corps du Génie en Europe.") In the U. S. the existing Corps of Engineers owes its origin to the act of Congress of Mar. 16, 1802, by which the President was authorized to organize and establish a Corps of Engineers, which was (ultimately) to consist of 1 colonel, 1 lieutenant-colonel, 2 majors, 4 captains, 4 first lieutenants, 4 second lieutenants, and a limited number of cadets (*i. e.* the *total* number not to exceed 20); and it was further provided, that the said corps, when so organized, shall be stationed at West Point in the State of New York, and shall constitute a Military Academy; and the engineers, assistant engineers, and the cadets of the said corps shall be subject at all times to do duty in such places and on such service as the President of the U. S. shall direct. Thus, by their common organic law the Corps of Engineers and the Military Academy were *identical*. The 63d Article of War (April 10, 1806) says: "The functions of the engineers being generally confined to the most elevated branch of military science, they are not to assume, nor are they subject to be ordered on, any duty beyond the line of their immediate profession, except by the special order of the President of the U. S.." etc.

Most of the officers of the newly-created Corps were soon called to duties along the seaboard in constructing our for-

tifications, while, as the wants of the service and of the Academy have become more clearly recognized, the number of cadets has been increased, to supply not only the Engineers and Artillery, but officers of all arms of the service; and the various professorships and departments of instruction now existing have been established at the Academy.

In 1838 (July 5) the Corps was increased to number forty-seven officers, and at the same time a corps of Topographical Engineers of about the same number (engineers under the designation having been before authorized) was organized. In 1846 (May 15) a company of "sappers, miners, and pontoneers" was authorized to be "attached to and compose a part of the Corps of Engineers, and be officered by officers of that corps, as at present organized; they shall be instructed in and perform all the duties of sappers, miners, and pontoneers, and shall aid in giving practical instructions in these branches at the Military Academy," etc. With some slight changes these corps were thus constituted at the commencement of the civil war. In 1861 three additional companies of engineer soldiers were authorized by Congress, which, with that already existing, were styled the "battalion of engineers;" and a company was also organized for the Corps of Topographical Engineers. In 1863 the latter corps was abolished, and its officers merged with the Corps of Engineers, the organization of which, as confirmed by the peace establishment of 1866, is one Chief of Engineers, with the rank, pay, and emoluments of a brigadier-general; six colonels, twelve lieutenant-colonels, twenty-four majors, thirty captains, and twenty-six first and ten second lieutenants. Under this organization the Corps of Engineers, embracing its commissioned officers and companies of sappers, miners, and pontoneers, constitutes a special arm of the service, and is charged with all duties relating to the selection, purchase, and survey of the sites, and the plan, construction, and repair of all fortifications, whether permanent or temporary, and their care when not garrisoned; with all channel and river obstructions, including torpedoes, required for coast defence; with all works for the attack and defence of places; with all fixed and movable bridges for the passage of rivers; with all lines, redoubts, intrenched camps, bridge-heads, etc. required for the movements and operations of armies in the field; and with making such reconnaissances and surveys as may be required for these objects. It is also charged with the survey, plan, and construction of harbor and river improvements; with military and geographical explorations, reconnaissances, and surveys, including the geodetic survey of the lakes; and with all engineer duties, confided to other departments than that of war, which may be specially assigned to the corps by acts of Congress or orders of the President of the United States.

By act of Congress of July 12, 1866, the Superintendency of the Military Academy, which had still been confined to the corps, was opened to all arms of the service; and at that date the intimate connection between the academy and the corps with which it was originally identified may be said to have terminated. The Corps of Engineers may truthfully be said to have made a record worthy of its title. As the Military Academy, it has been the "nursing father" of the U. S. army. Among its chiefs and superintendents we find in Williams, Swift, Armistead, Macomb, Totten, Thayer, etc. names identified with our military history, and conspicuous for their services in the field as well as in peace. During the Mexican war its officers rendered conspicuous services, recognized and mentioned by Generals Scott and Taylor, while in our civil war the names of Meade, McClellan, Halleck, McPherson (killed), Humphreys, Rosecrans, Meigs, Gillmore, Cullum, Benham, Warren, Woodbury, Tower, Wright, Newton, Alexander, Foster, Morton (killed), Franklin, W. F. Smith, Michler, Parke, Abbot, Poe, Duane, Comstock, Weitzel, Reese, Babcock, Cross (killed), O'Rorke (killed), John R. Meigs (killed), Michie, etc. stood conspicuous; and some of the ablest of the Confederate officers, Lee, Beauregard, J. E. Johnston, etc., had been officers of the corps. In its services to science it claims the Academy, the *great* superintendent of which, Sylvanus Thayer (recently deceased), is with justice styled the "father of the Military Academy." The names of Bache, Bailey, Davies, Bartlett, Church, Mahan, Webster, Mitchell, Norton, F. H. Smith, Ewell, etc. are evidences of its influences upon science and educational institutions. In the development of the country by works of civil engineering it has had no insignificant share, and the names of J. G. Swift, Long, McNeill, W. H. Swift, Totten, Abert, Douglass, Turnbull, etc. are among those of the fathers of American engineering. Finally, in its own peculiar sphere, the devising and constructing of our great system of sea-coast defences (of which it may be said to be the first to lay down principles, as distinct from those of the somewhat pedantic art of "fortification" of the text-books), and in its numerous works of harbor and river improvement and in the Delaware Breakwater, it has erected enduring monuments of its services.

J. G. BARNARD, *U. S. Army.*

Engineers in the U. S. Navy are non-combatant commissioned officers who have charge of the machinery of steam vessels. Engineers are not only required to be practically acquainted with the management of nautical steam-machinery, but they must be good mechanics, capable of superintending necessary repairs; and they are further required to have acquaintance with the physical properties and powers of steam, and with the collateral departments of science. There are first and second assistant engineers, who are also commissioned officers.

England [Lat. *Anglia;* Fr. *Angleterre;* Ger. *England*], the southern and larger division of the island of Great Britain, and the principal member of the United Kingdom of Great Britain and Ireland. All that belongs to the United Kingdom at large, its geography and statistics, as well as its history from the time when the permanent union of Scotland with England and Ireland united the three countries into one empire, will be treated of under the head of GREAT BRITAIN, while in this article we shall confine ourselves to what is peculiar to England and to its history up to the time of the union.

England is bounded on the N. by Scotland, E. by the German Ocean, S. by the Straits of Dover and the English Channel, S. W. by the Atlantic, and W. by St. George's Channel and the Irish Sea. It is situated between lat. 49° 57′ 30″ and 55° 47′ N., and lon. 1° 46′ E. and 5° 41′ W., the greatest length N. and S. being 400 miles, and the greatest breadth 280 miles. In shape it resembles a triangle, of which Berwick may be considered the apex, and a line from the Land's End to the North Foreland the base. The sea-coast, if measured from one headland to another, is about 1200 miles; if the principal indentations are followed, about 2000 miles. The area amounts to 58,320 square miles, of which 7397.6 belong to Wales and 50,922.4 to England proper. Taken by themselves, England and Wales are more densely populated than any other European country except Belgium, the average population of a square mile amounting to 389. Since the beginning of the present century the population has increased about 150 per cent. It amounted in 1801 to 8,892,536, in 1831 to 13,896,797, and in 1871 to 22,704,108. Since the days of the great Alfred the country has been divided into counties or shires, and these again generally into hundreds, and always into parishes. The northern counties are divided into wards, instead of hundreds; Kent and Lincoln, into lathes and sokes; and York, into ridings, each of which is regarded as a county by itself. The following table exhibits the area in statute acres (640 acres = 1 square mile) and the population of each of the fifty-two counties at the date of the census of 1871:

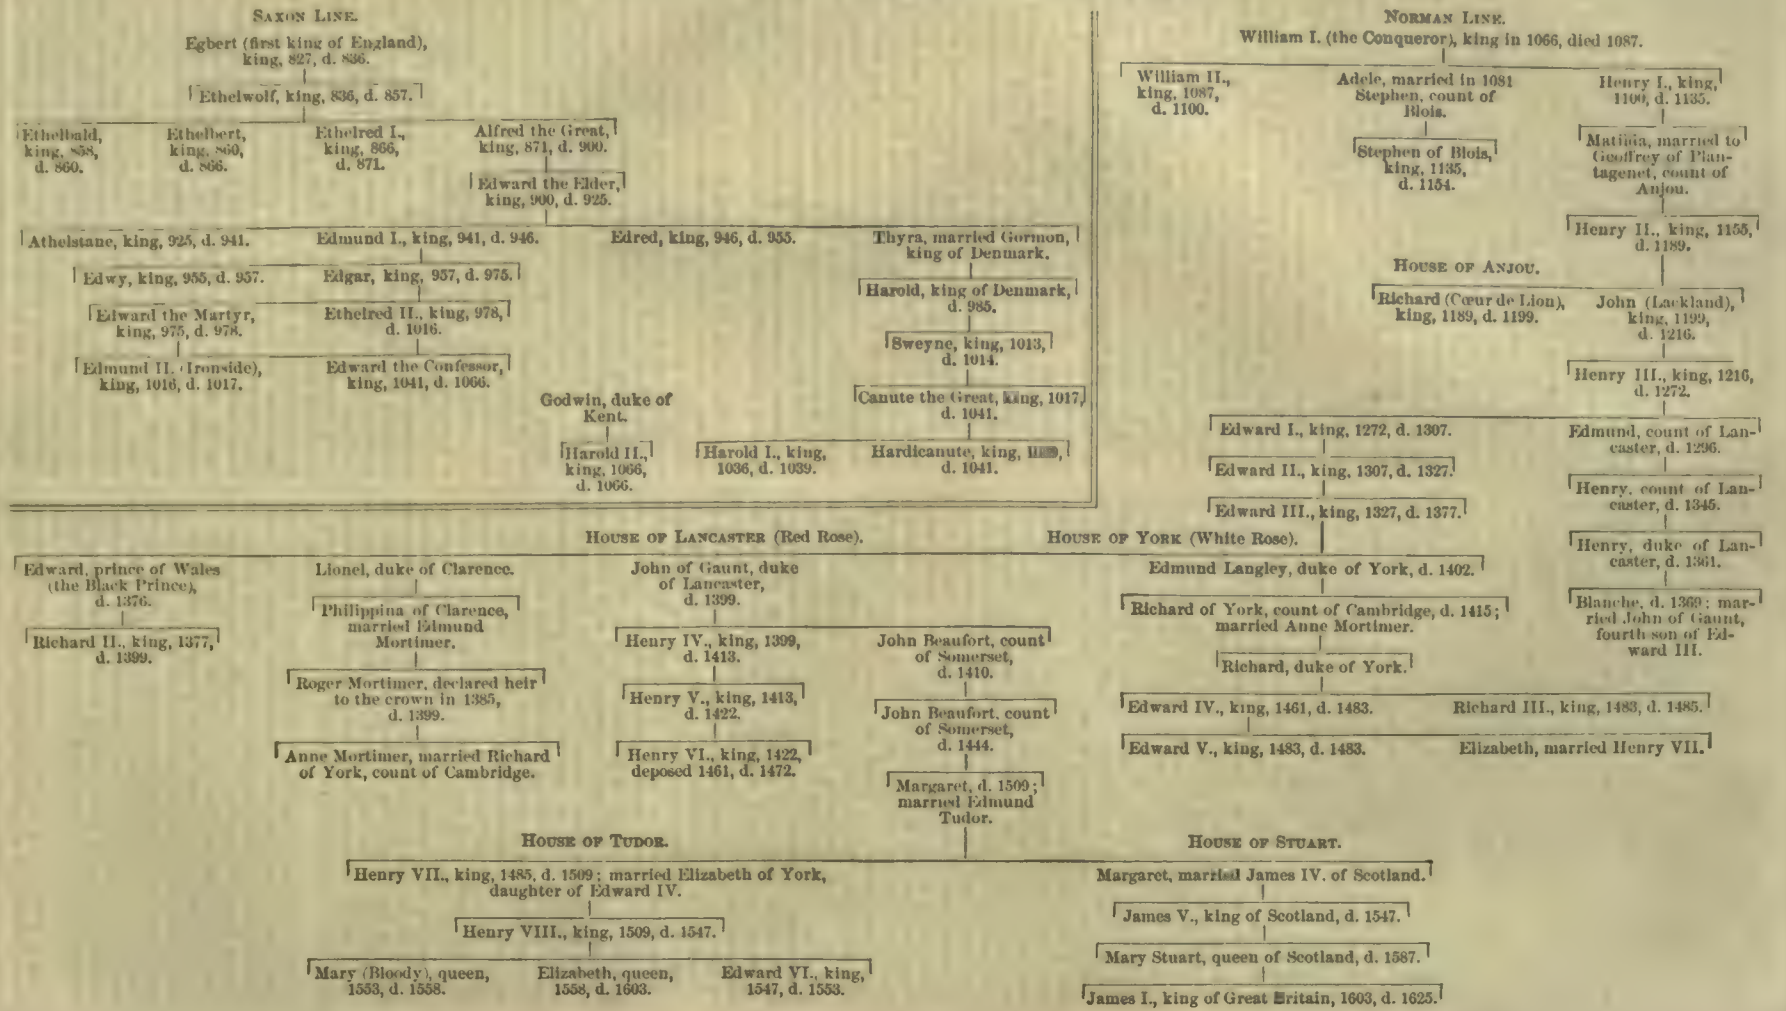
During the last twenty years the urban districts have grown much more rapidly in population than the country districts; and while in 1851 the population of 141 districts and 57 sub-districts, which included the chief towns, was 9,155,964 to 8,771,645 of the rural districts, which contained the small towns and the rural parishes, the population of the former had in 1871 risen to 12,900,297, against only

9,803,811 of the latter. No country of Europe has so large a number of populous cities as England. London, with its more than 3,000,000 inhabitants, contains one-fourth of the entire urban population of the country, which, besides, had in 1871 eleven other towns with a population of upwards of 100,000 inhabitants—namely, Liverpool, Manchester, Birmingham, Leeds, Sheffield, Bristol, Bradford, Newcastle-on-Tyne, Salford, Hull, and Portsmouth. The number of births in 1871 was 797,143; of deaths, 515,000; of marriages, 190,000. The proportion of male to female children born is as 104,811 to 100,000; the equilibrium between the sexes is restored about the tenth year of life, and is finally changed, by emigration, war, and perilous male occupations, to the extent that there are in all about 100,000 women to 95,000 men in England and Wales.

England and Wales have their own State Church, which is different from the State Church of Scotland, while Ireland at present has no State Church at all. The sovereign of England is by law the supreme governor of the Church of England, possessing the right to nominate or to appoint to the vacant archbishoprics and bishoprics. The Church has in England 2 archbishops, 26 bishops, and about 12,000 parishes. No information concerning the membership of the Church of England, or any other religious denomination of England, is given in the official censuses of 1861 and 1871. The estimates of the population connected with the Established Church differ from 12,700,000 (Martin, "Statesman's Manual" for 1873) to 17,781,000 (Ravenstein, "Denominational Statistics of England and Wales," London, 1870). The number of Roman Catholics is estimated at from 2,000,000 (Martin) to 1,058,000 (Ravenstein). The entire number of sects having places registered for the performance of divine worship was, on Oct. 1, 1872, 125, and the entire number of registered places of worship, 18,996.

History.—England was undoubtedly known to the Phœnicians, Carthaginians, and Massilians, all of whom are supposed to have traded with it; but its real history does not begin until the establishment of the Roman rule by Cæsar in 55 B. C. The rule of the Romans, who called the present island of Great Britain *Britannia*, lasted till the beginning of the fifth century, when they withdrew. (See Britannia.) In consequence of the inroads of the Picts and Scots from the north, and the quarrels of the British chiefs among themselves, the country appears to have soon become a prey to complete anarchy. A British prince of Kent, Vortigern (Gwrtheyrn), is said to have been the first to secure the aid of two Saxon chiefs, commonly called Hengist and Horsa, in his struggles against the northern invaders. The statements as to the first appearance of the Saxons in England are conflicting and untrustworthy, and even the names of their leaders are considered by some historians as fabulous. Certain it is, that in the course of about 130 years the Saxons, Jutes, and Angles completed the conquest of the greater part of England, establishing three Saxon kingdoms (Sussex, Wessex, and Essex), one Jutish (Kent), and four Anglian (Bernicia, Deira, East Anglia, and Mercia). The British maintained for a somewhat longer period five states (Strath-Clyde, Cumbria, North and South Wales, and Cornwall). Egbert, king of Wessex, is commonly believed to have become about 830 the first king of all England. During his reign the invasions of the Danes began, who for a period of twenty-four years (1017–41) became masters of the kingdom. In 1041 the crown again devolved on an Anglo-Saxon prince, Edward the Confessor, but his authority was little more than nominal, six powerful earls, Danes and English, dividing the country between them. At his death, in 1066, Harold, earl of Wessex, seized the throne by force, but in the decisive battle of Hastings (Oct. 14, 1066) against another claimant to the throne, William, duke of Normandy, he was defeated and killed. With the reign of William, surnamed "the Conqueror," a new era of English history begins. The lands were divided into 60,000 knights' fees or estates among the followers of the Conqueror as feudal lords, and thus on the solid basis of extensive landed estates the firm foundation was laid of a powerful aristocracy, which amidst the social revolutions of centuries has more successfully defended its ascendency than that of any other country of Europe. The population of England at this time appears to have been from 2,000,000 to 3,000,000, and about 100 boroughs were governed by municipal customs or under the protection of the kings, nobles, or prelates, from whom in after times they purchased their franchises. In the course of time the distinction between the Norman conquerors and the conquered Saxons passed away, and from their union arose the English people as it now exists. The Norman line gave to England only three kings—William I. and his two sons, William II. and Henry I. The death of the latter in 1135 was followed by a war of succession between Stephen of Blois, his nephew, and his only daughter, Matilda, who was married to Geoffrey of Anjou. In 1155 the son of Matilda, Henry II., was generally recognized as king of England. He was the founder of the house of Plantagenet, which in direct line ruled in England until 1485. Henry possessed, besides England, the provinces of Anjou, Touraine, and Maine in France, to which he added Guienne and Poitou by marriage and Brittany by conquest. He conquered Ireland in 1171, and by the Constitutions of Clarendon in 1164 curtailed the privileges of the Church, but was forced, in consequence of the assassination of Archbishop Becket, to make his peace with the Church. He was in 1189 succeeded by his eldest son, Richard I. ("Cœur de Lion"), who distinguished himself in the Crusades, but could not prevent the nobility from increasing their power at the expense of the crown. The reign of his younger brother, John ("Lackland," 1199–1216), is one of the most inglorious in the English annals. He lost nearly all the possessions of the English sovereigns in France, and in 1213 consented to hold the English crown as a gift from Rome. His weakness, however, had some good results for the people of England. The separation of the Normans of England from those of France hastened the consolidation of the English nation; and when involved in disputes with the pope, he had to conciliate the barons, who were backed by the people, by the concession of the celebrated Great Charter (*Magna Charta*), signed at Runnymede in 1215. The charter secured to the English people, in advance of any other people of Europe, two great rights—that no man should suffer arbitrary imprisonment, and that no tax should be imposed without the consent of the council of the nation. When John showed an unwillingness to carry out some of his promises, the barons called Louis of France (son of the king, Philip Augustus) to their aid, who conquered a large portion of the country, but was compelled, soon after the death of John (Oct. 17, 1216), to make peace and renounce the project of annexing England to France. But while the national pride of the English people successfully prevented its subjection to France, anarchy rapidly increased during the reign of John's son, Henry III. (1216–72). As Henry at the death of his father was only a boy of nine years, the government was carried on first by the earl of Pembroke, and after his death by Hubert de Burgh and the bishop of Winchester, neither of whom was able to check the demands of the nobility for greater power. When Henry assumed the government himself, an open war with the barons soon broke out, who extorted from the king an enlargement of the Great Charter, and in 1264 took him and his eldest son, Edward, captives. The next year the first English Parliament was convened by the leader of the rebels, the earl of Leicester; but soon Prince Edward, who had been set free, broke the power of the barons in the battle of Evesham, in which the earl of Leicester fell, and restored the authority of the king. Henry deemed it, however, best to pursue a conciliatory policy, and in particular to confirm the Great Charter. Edward I. (1272–1307) had sufficient energy and statesmanship to put an end to the confusion into which the country in the latter years of his father's reign seemed to relapse, and considerably promoted the consolidation of the kingdom. He conquered in 1283 the last prince of Wales, and united this country, which thus far had been semi-independent, for ever with England, conferring on his eldest son the title of prince of Wales, which has ever since been borne by the eldest son of the English sovereign. He obtained a decisive victory over Scotland in the battle of Falkirk (1299), but under the leadership of Wallace, Comyn, Fraser, and Bruce the Scotch saved their independence. In a war with France the last English possession on the Continent, Guienne, was lost, but it was restored through the mediation of the pope. For the development of the English constitution his reign was of the greatest importance, as the council of the realm assumed a form resembling that of the modern Parliament by the separation of the greater barons from the tenants in chief, the latter ceasing to be summoned to Parliament, and being present only through their representatives. The first sitting of the Commons in a separate chamber took place in 1295, and in the following year the famous statute was passed that no manner of tax should be imposed without the common consent of the bishops, barons, and burgesses of the realm. Edward II. (1307–27) lost the footing which his father had gained in Scotland, and was finally dethroned by the prelates and nobles, who assumed the power of a Parliament. The reign of his son, Edward III. (1327–77), is regarded as one of the most brilliant periods of English history. His claim to the throne of France involved him in a war which, with few interruptions, lasted from 1337 to 1374, and which, notwithstanding the brilliant English victories of Cressy (1346) and Poitiers (1364), finally led to the surrender by the English king of all the English possessions in France, except Bordeaux, Bayonne, Calais, and a district of Gascony. The great expenditures required by the



war made the king dependent on his Parliament, which henceforth was directed by statute to be summoned annually. Another important result of the war was the entire fusion of the Normans and Saxons into the English nationality. The spirit of chivalry attained at the court of Edward its highest point of exaltation, but on the other hand the laboring-classes made their power felt for the first time; for as their service had become more valuable in consequence of the terrible ravages of the great pestilence in 1349, they demanded and received higher wages, and a series of despotic edicts ordering them to work at the former wages proved entirely inefficient. During the reign of Edward, Wycliffe began (about 1360) his attacks upon the abuses in the Church, and he was supported by Edward's fourth son, John of Gaunt, and by some of the principal nobility. As the king's eldest son, Edward, prince of Wales, known as the "Black Prince," died one year before his father (1376), the latter was succeeded by his grandson, Richard II. (1377–99), during whose weak reign an attempt to enforce the tyrannical labor laws brought on the famous rebellion of the peasantry under Wat Tyler, which, though suppressed with much bloodshed, relaxed the servitude of the peasantry. Richard was dethroned by his cousin Henry, duke of Lancaster, who ascended the throne as Henry IV. (1399–1413). His reign, which was greatly disturbed by rebellions and conspiracies, is remarkable for two events in the history of the English constitution—the fixing by statute of the parliamentary right of election for counties in all freeholders (afterwards restrained under Henry VI. to those who were worth forty shillings per annum), and the recognition of the two houses as bodies possessing distinct privileges, not to be interfered with by each other. The religious reformation of Wycliffe found in Henry a determined opponent, the act for the punishment of heretics under which so many atrocities were committed for nearly two hundred years being passed during his reign (1401). His son, Henry V. (1413–22), put down the religious movement of the Lollards with a strong hand, and renewed the claims of his ancestors to France. The new war between the two countries was favorable to England; Henry entered Paris, and on his death a large portion of France recognized, with England, his son, Henry VI. (1422–61), then only a boy of nine months, as king. After many campaigns the French were, however, ultimately successful, the exploits of Joan of Arc, Count Dunois, and other French leaders putting for ever an end to the English attempts to conquer France. Soon after that terrible civil war known as the war of the Red and White Roses began (see Roses, Red and White), Richard, duke of York, a descendant of the duke of Clarence, third son of Edward III., claimed a title to the throne preferable to that of King Henry, on the ground that the latter was only a descendent of the fourth son of Edward III., and that the pretensions of the king's grandfather, Henry IV., to be descendant from Edward, earl of Lancaster, according to popular tradition the eldest son of Henry III., and excluded from the succession on account of deformity, were apocryphal. Richard, duke of York, fell in the battle of Wakefield, Dec. 30, 1460, leaving his claims to his eldest son, Edward, the earl of March, a youth of nineteen, who was proclaimed king as Edward IV. in 1461, and maintained himself until his death (1483), with a short interruption (1470–71), when the rebellion of the earl of Warwick, formerly the most prominent among his supporters, compelled him to flee to Holland, and restored for the time Henry VI. The son of Edward (Edward V.), a minor, was after a reign of only thirteen days dethroned by his uncle, the duke of Gloucester, placed in confinement, and soon disappeared. The usurper made himself king under the name of Richard III. (1483–85), but soon a coalition of disaffected Yorkists and of the Lancastrians was formed against him, at the head of whom was Henry Tudor, earl of Richmond, who through his mother descended from the House of Lancaster, and to satisfy the Yorkists was to marry Elizabeth, the eldest daughter of Edward IV. In the decisive battle of Bosworth Field, in 1485, Richard lost his crown and his life, and Tudor ascended the throne as Henry VII. With him a new era begins in English history. The first years of Henry (1485–1509) were greatly disturbed by pretenders to the throne, who, personating the head of the House of York, claimed to be the legitimate heirs to the crown. But the chief feature of his reign is the large increase of the royal power at the expense of the high nobility and the Parliament. Many of the principal nobles having perished in the wars of the Roses, Henry succeeded in enforcing against the barons the laws forbidding them to give badges and liveries and to employ retainers. The change thus produced in the relation of the nobility to royalty became still greater from the fact that the former began to value money-payments from their tenants and dependants higher than personal services, while the lower classes of the people began to understand that hereafter they had to support themselves and to respect the laws, instead of looking to the nobility for support and for impunity in case they had committed lawless acts. The great event in the reign of his son, Henry VIII. (1509–47), was the separation of the Church of England from Rome. Henry was a violent opponent of Luther and the German Reformation, but when the pope refused to grant him a divorce from his wife, Catharine of Aragon, he renounced his communion with the pope and assumed the title of the Head of the Church. (See England, Church of.) His only son, Edward VI. (1547–53), succeeded at the age of nine years, and the country thenceforth was governed by a council of regency favorable to the Reformation, which now advanced from questions of government to questions of doctrines. The duke of Northumberland, who had caused one of his sons to marry Lady Jane Grey, great-granddaughter of Henry VII., caused Edward to bequeath the crown to his daughter-in-law; but the reign of Lady Jane lasted only ten days, when Mary (1553–58), the daughter of Henry VIII. and his first wife, Catharine of Aragon, ascended the throne. Mary was a devout Catholic, who obtained the consent of her Parliament to repeal (1553) the legislation of Edward VI. and that (1555) of Henry VIII., thus re-establishing the papal authority. When the chiefs of the Protestant party opposed the counter-reformation more than 200 of them suffered at the stake. Her marriage with Philip II. of Spain did not, however, save to the Catholic Church its ascendency in England, for Mary died in 1558 without issue, and on the other hand it cost England the last possession in France, Calais, which was taken by the duke of Guise. Mary was succeeded by her half-sister, Elizabeth (1558–1603), the daughter of Henry VIII. by his second wife, Anne Boleyn, who was strongly opposed to the supremacy of the pope, by whom she had been declared to be a bastard. Parliament in 1559 restored the royal supremacy of the Church, which, by the adjustment of the Prayer-Book and the Thirty-nine Articles, substantially received the form in which it still exists. The power of the Roman Catholics in England was completely broken; and when most of them embraced the cause of Mary, queen of Scotland, who, on seeking an asylum in England, had been imprisoned, Elizabeth ordered Mary to be executed. Abroad, she aided the Protestants of France and the Netherlands, and the crushing defeat of the Spaniards, whose Armada was destroyed in 1588, elevated England to a higher position among the countries of Europe than she ever had had before. Ireland was reduced to a state of entire submission, and the commerce and naval power of the country received a wonderful impulse by the establishment of commercial intercourse with India. Elizabeth was the last sovereign of the House of Tudor; she was succeeded by James VI., the son of the unfortunate Mary. Thus England, Scotland, and Ireland became united under one sovereign; and although the legislative union with Scotland was not consummated until 1707, and that of Ireland not until 1800, the three countries were, in fact, one empire, whose subsequent history is treated in Great Britain and Stuart.

Chronological Table of the Sovereigns of England from the Conquest to James I.

Kings and Queens.	Reigned.	Age.
Norman Line.		
William the Conqueror	1066–1087	60
William Rufus	1087–1100	43
Henry I.	1100–1135	67
Stephen of Blois	1135–1154	49
House of Plantagenet.		
Henry II.	1154–1189	55
Richard I.	1189–1199	43
John	1199–1216	60
Henry III.	1216–1272	65
Edward I.	1272–1307	67
Edward II.	1307–1327	43
Edward III.	1327–1377	65
Richard II.	1377–1399	33
House of Lancaster.		
Henry IV.	1399–1413	46
Henry V.	1413–1422	33
Henry VI.	1422–1461	49
House of York.		
Edward IV.	1461–1483	41
Edward V.	1483–1483	12
Richard III.	1483–1485	42
House of Tudor.		
Henry VII.	1485–1509	52
Henry VIII.	1509–1547	55
Edward VI.	1547–1553	15
Queen Mary	1553–1558	42
Queen Elizabeth	1558–1603	69
House of Stuart.		
James I.	1603–1625	59

A. J. Schem.

Genealogical Table of the Kings of England, from Egbert to James I.

England, Church of, that portion of the Christian Church which has existed in England since the time of Saint Augustine (A. D. 597). The title is also sometimes given to the English Church with reference only to the period since the Reformation, but with no great accuracy, since the Church of England, like the other national churches of Europe, is, both in law and fact, a continuous body. Christianity was introduced into England, if not in the days of the apostles, at least very soon after them; and it speedily made its way even beyond the limits of the Roman settlements. The abandonment of Britain by the Romans, the invasion of the Saxons, and the consequent neglect or persecution of the native Christians, gave a serious check to the progress of the infant Church, and in the sixth century its influence was limited to the northern parts of the island, whither many of the Britons had retired to escape from the invaders. The mission of Augustine, however, was strictly to the heathen Saxons. Pope Gregory the Great had contemplated undertaking this mission in person, but upon his elevation to the papal throne had been compelled to abandon his design. Augustine (or Austin), prior of St. Andrew's monastery at Rome, was selected as his substitute. After a brief delay in France, where he was consecrated bishop by Vigilius of Arles, Saint Augustine arrived in Kent in the autumn of 596. His labors were crowned with success. The conversion of the kingdom of Kent was followed by the triumph of Christianity in all the kingdoms of the Heptarchy. The influence of the Italian missionaries, however, did not extend far, if at all, beyond the limits of the kingdom of Kent. The whole northern part of England was converted by British and Irish clergy. There was also, for many years, much jealousy between the native and foreign churchmen, but in process of time the two missions melted into one church; and it has long been customary to date the historical beginning of the Church of England and the succession of its prelates from the foundation of the see of Canterbury by Saint Augustine (A. D. 597).

At that time there was but one Christian Church, and the doctrines of the Church of England were of course the common faith of Christendom. In considering, as will be done presently, the events of the sixteenth century in England, it should be borne in mind that the abuses which were then removed had no existence in the sixth. The primacy of the pope had not then developed into a supremacy, but, as appears from the letters which passed between Gregory the Great and Saint Augustine, the authority of the former was limited to giving advice and counsel. The controversies about image-worship, which gave occasion to the Councils of Nice and Frankfort, did not reach their height until the eighth century. The mediæval teachings of purgatory and pardons were not fully developed until the twelfth, and the growth of the idea of papal supremacy was necessarily kept in check by the Eastern patriarchs until the eleventh. The final impetus was given to its growth by the separation of the Eastern and Western churches, and the general acceptance in the West of the pseudo-Isidorian Decretals.

As time went on these teachings made progress in England, as they did in the rest of Western Europe. As the papal authority took the obnoxious form of claiming a right to confirm the nominations of bishops and to hear appeals, it was met with frequent and vigorous opposition—not only in England, but also in the other kingdoms of Europe. Appeals to Rome had been prohibited in England from a very early period, and a vacancy in an episcopal see was apt to lead to a protracted controversy between the pope and the reigning sovereign, neither of whom was willing to admit the pretensions of the other.

When in the reign of Henry VIII. the Church and Parliament of England resolved to put an end to appeals to Rome, and to the claims of the pontiffs to a right to confirm the nominations of bishops (which, under certain circumstances, had been stretched into a claim to nominate in the first instance), they conceived that they were merely reasserting those ancient rights of the Church of England which, though they had been suffered to fall into disuse, had never been abandoned. This position was taken with great unanimity, and was adhered to consistently by Bishop Gardiner and the national (or, as it might now be called, the old Catholic) party in England. The king was drawn into the violent measures of the dissolution of the monasteries and the spoliation of the Church by other counsellors.

The efforts of the Church of England to regain its ancient liberties were contemporaneous with, though distinct from, the continental Reformation. That event, however, was not without its influence in England; and in the reign of Edward VI. men who sympathized with Luther or Calvin, or even with the teachings of Zuinglius, had gained control over the English Church and nation. Under their influence, indeed, England was becoming rapidly Protestantized; and, in all likelihood, had not their career been cut short by the death of the king, the religious condition of England would have been much the same as that of Switzerland or Scotland.

The accession of Queen Mary led to a violent reaction. The Protestant school of Cranmer and Ridley was forcibly suppressed, and the national party, of which Gardiner was the leader, was compelled to change its ground. The authority of the pope was restored in more than mediæval plenitude. Attempts were made not only to revive the state of things which existed in the early part of the reign of Henry VIII., but actually to destroy the ancient liberties of the Church of England. It is a grave question among historians whether Edward or Mary, both acting doubtless from the most conscientious motives, would, had their reigns been prolonged, have done more serious injury to the Church.

Queen Elizabeth, on coming to the throne, found herself encompassed with difficulties. There were then three schools or parties in the English Church: first, that of Gardiner and his followers, which had changed its ground, and was now disposed to maintain the papal supremacy, with all that it involved; second, that of Parker, which went beyond the former national school in its desire to reform what it believed to be abuses; and third, the Protestants, many of whom had taken refuge in Switzerland during the reign of Mary, and who returned full of admiration of the form of religion which they found established there, and anxious to introduce it into England. The private opinions of the queen, if indeed she had formed any, were not distinctly known, and it was for some time doubtful to which school she would give her influence and approbation. It may seem strange to minds educated in the ideas of the present age that the religious belief of great nations should have been directed or influenced by the private opinions of their sovereigns; but in the sixteenth century, and even later, the Church formed a part of the constitution of the nations of Western Europe. There was no idea that there could be more than one religious society in a nation, and therefore no idea of toleration or religious liberty. The history of England in the sixteenth century is not different from that of other European states. If the civil authority could carry out a reformation of religion in England and Sweden, it could suppress it in France and Spain and Italy.

Thus it was the purpose of any party that might succeed in gaining the favor of the queen to become not merely dominant, but exclusive. Its peculiar views were to be forced on all men. The Protestant (or, as it was soon afterwards called, the Puritan) school speedily put itself out of the question by the fact that its teachings would have led to the destruction of the Church of England, and the establishment of a new form of religion upon the plan adopted at Geneva. Various circumstances tended to alienate the queen from the papal (or, as it began to be styled, the Roman Catholic) party. The haughty discourtesy with which Pope Paul IV. received the information of her accession, which she sent to him in the usual form; the assumption of the title of queen of England by Mary of Scotland, with the great probability that France and Spain would proceed to assert the claims of the Scottish queen by force of arms; and the persistent attitude of opposition to all reforms maintained by the Marian bishops, compelled Elizabeth to put herself in the hands of the national or reforming party, of which Matthew Parker was the acknowledged leader. Like the national party in the reign of Henry VIII., this school was prepared to remove the jurisdiction which the pope had exercised within the realm of England. Like those earlier leaders, it desired to preserve the faith and discipline of the Church unaltered, but it went beyond them in proposing to remove certain abuses of teaching and practice which it conceived had led the people into superstition. These were the use of images, the invocation of the saints, the popular idea of purgatory, and the peculiar definition of the manner of the Real Presence in the blessed sacrament which is known as transubstantiation. These were doubtless developments, but, in the view of the school of thought which became dominant in England, unlawful developments of true doctrines. The Reformers thought that they could trace the progress of variation from the simpler teachings of the earlier Church, and their purpose was to carry back the Church of England, as nearly as possible, to its primitive simplicity. Whether they succeeded or not is a question which need not be now discussed; it will be sufficient to say that they proceeded to carry out their plans with promptitude and vigor. Parker was made archbishop of Canterbury in the place of Pole, who had died almost at the same time as Queen Mary. The majority of the bishops, refusing to co-operate with him, were removed or resigned their sees, and their places were filled by men whom he could trust. Attention was at once given to the reform of the service-books of the Church. Two prayer-books, compiled partly from the old Latin Uses of the Church of

England, had been set forth in 1549 and 1552, but had been suppressed in the reign of Mary. After much deliberation, it was determined to make the second of these the basis of the Prayer-Book, which was henceforth to be in English. The reforms in doctrine to which allusion has been made were indeed carried out, but care was taken to avoid touching any part of the common faith of Christendom. The famous principle of Vincent of Lerins, of universal acceptance as the test of Christian truth, was affirmed, and the authority of general councils was acknowledged. These arrangements received the approbation of Convocation and Parliament. Concessions had been made to both the extreme parties—to the Puritans, in adopting the second instead of the first prayer-book of Edward VI.; to the Roman Catholics, in leaving out certain expressions which were justly obnoxious to them—and it was thought that religious unity would thenceforward prevail in England.

This settlement, the joint work of Convocation and Parliament, was accepted by the great body of the nation; and, since all men continued to frequent the parish churches for about ten years, it was hoped that the unity of the English Church would continue unbroken. In 1570, however, after the excommunication of Queen Elizabeth by Pius V., the party afterwards called Roman Catholics, acting under the direction of the pope, separated from the Church. In those ages politics and religion were so singularly intermingled in Western Europe that any religious agitation commonly involved plots and treasons against the state, and sometimes open war. In this respect England was no better nor worse than other countries; and in this condition of affairs the true motive is to be found for the stringent laws which were enacted and put in force against "popish recusants." The penal laws, however, were the work of the State rather than of the Church; and they were intended not as a measure of unnecessary persecution, but as a precaution against the plots for the destruction of queen and government, which followed one another in quick succession.

Some of the extreme Protestants followed the example of separation in 1580 under the leadership of Robert Brown, who, however, returned to the Church and died in its communion. They were known at first by the name of Brownists, afterwards as Independents, and finally as Congregationalists. Others remained in the Church and demanded a further reformation, which, however, has never been conceded. The Prayer-Book has indeed been twice reviewed, but the tendency on both occasions has been to bring it into nearer accordance with the first book of Edward VI., which is supposed to have contained the true sentiments of the earlier Reformers.

The remaining history of the Church of England may be passed over briefly. After its suppression during the civil war—the success of which has, by some writers, been attributed to a temporary though secret combination between the extreme sections of its enemies—it was restored in 1660, since which time no change has been made in its doctrine or discipline. The exciting scenes of the sixteenth and seventeenth centuries, the successive attempts to restore the supremacy of the pope, culminating in the ill-advised measures of James II. and the consequent irritation of the people, led, first, to a reaction, and after the revolution of 1688 to a long period of religious indifference. The latter part of the seventeenth century was an age of immorality; the earlier part of the eighteenth was a time of negligence and indifference. Since the middle or early part of the eighteenth century there have been three great religious revivals. The first was that of John and Charles Wesley, both priests of the Church of England, who set themselves to the task of developing personal holiness (the great want of an age of religious indifference and immorality) in the members of their Church. Their labors were crowned with great and immediate success; but, partly by reason of the absence of encouragement from the leaders of the Church, and partly from the impatience of some of their own followers, they failed in accomplishing their designs. The Wesleys themselves lived and died in the communion of the Church, but many of their followers withdrew from it and formed a new body of dissenters.

The second revival was that of the "Evangelicals," as they were called, about 1798, of which such men as the Rev. Charles Simeon and the late Bishop Daniel Wilson were the leaders. The guiding thought in this movement also was the development of personal holiness. The movement was well adapted to the times, and may be regarded as successful while it lasted, but it lacked the elements of permanence. Its weakness lay in neglecting definite dogma, which experience has shown to be essential to any form of religion. The work of these good men, however, is worthy of all reverence. They accomplished a great deal in their generation, and they prepared the way for the revival which is now in progress.

While the aim of the Oxford divines, as they were called, was, equally with the others, the development of personal holiness, they endeavored to avoid the tendency of the first to schism, and of the second either to neglect dogma altogether or to give undue prominence to one or two points of Christian doctrine. Hence, they naturally dwelt much upon the authority of the Church; and their object seems, in their early history (1833–63), to have been simply to teach the Church to carry out in practice the doctrine, discipline, and manner of life which are set forth in the Prayer-Book. Of late years, however, the leaders of this school have given much thought to the relations of the Church of England to the rest of Christendom, and to the question of the restoration of visible unity among Christians. These points are discussed in the "Eirenicon" of the celebrated Dr. Pusey. Hence, much attention has been given to the study of church history, and the history of the English Church may be said to have been re-written within the last thirty years.

Both these schools still exist, and are commonly known as Low Church and High Church. The former claims, and no doubt justly, to be the representative of the Protestant or Puritan part of the Church in the reign of Elizabeth; the latter, of the Catholic or national school, which then gained the predominance, and, with the exception of the forty years of the evangelical revival, has always retained it. The peculiar character of the former is its claim to great liberty of private judgment; of the latter, its deference to authority. With the exception of a small party which has lately arisen, of which Dean Stanley is one of the leaders, and which is somewhat eclectic in its teachings, these two great historical schools may be regarded as comprising the whole Church of England.

The discipline of the Church of England has continued unchanged for many centuries. The bishoprics, with the addition of two or three which were created by Henry VIII., and those of Ripon and Manchester, erected within the present century, still remain in their ancient seats; and the succession of the bishops, of whom lists are extant, is traced in them to the sixth or seventh century. England and Wales are divided into two provinces, under the archbishops of Canterbury and York. The former has under him twenty bishops, the latter six. The episcopal incomes amount to £154,200. The population of the province of Canterbury in 1872 was about 15,742,404; of York, 7,174,638. In the former there were 4,374,880 church sittings; in the latter, 1,326,820; making a total of 22,917,042 for the population, and of 5,701,700 for the sittings. The actual church population is about 12,500,000. The system of parishes introduced by Theodore, the seventh archbishop of Canterbury (668–693), still exists. There were in 1872 12,837 parish priests and 6187 curates. The canon law, derived from the acts of successive English councils, still forms the basis of the ecclesiastical system. The revenues of the Church have been estimated at £5,000,000.

The great achievement of the English Church during the present century has been the establishment of the colonial episcopate. This began with the sending of Bishop Heber to Calcutta in 1814; there were in 1872 fifty-four dioceses in the English colonies and in missions. There are 1977 clergymen, and the income of the bishops is about £53,718. The amount raised in England for missions in 1871 by the members of the Church alone was £324,782, most of which was expended in the colonies. The total amount of British contributions for foreign missions in the same year (including those of nonconformists and of Scotch and Irish societies) was £855,742.

From time immemorial the archbishop of Canterbury has been held to be entitled to the dignity, though he has never borne the name, of a patriarch. That this is something more than an empty dignity would seem to be implied by the unanimity with which the late Archbishop Longley was accepted as the president of the conference or synod of bishops which sat at Lambeth in 1867, and by the general disposition to consider him as the spiritual head of the Anglican communion. This includes the Church of England (with Wales), of Ireland, the Church in the colonies, and the Episcopal churches in Scotland and in the United States of America. These churches, while they are one in doctrine, regulate their internal affairs for themselves, yet they may meet, as they have done once, in a synod of their bishops when any question of general interest arises. The whole number of episcopal sees and jurisdictions, as at present arranged, is 150, though the actual number of bishops is a little larger.

BEVERLEY R. BETTS, *Lib. of Columbia Coll.*

Eng'land (JOHN), D. D., was born in Cork, Ireland, Sept. 23, 1786. He was educated at Carlow College, and took orders in the Roman Catholic Church in 1808. He was greatly distinguished for his zeal, his benevolence, and his bold championship of Catholic emancipation. He was

also a prominent journalist, and was once fined £500 for his boldness in discussing political questions. In 1820 he became bishop of Charleston, S. C., and there founded the "Catholic Miscellany," the first journal of his Church in America. Died April 11, 1842. His works, in 5 vols. 8vo, appeared in 1849. Bishop England's heroic behavior during an epidemic of yellow fever in Charleston endeared him to all classes of citizens. He was a man of great energy, profound learning, and much zeal for his Church, but possessed kind and liberal feelings for those who had views unlike his own.

England (Sir Richard), G. C. B., a son of Lieut.-Gen. Sir Richard England, an officer of Irish origin, distinguished in the British service during our Revolutionary war. The younger Sir Richard was born at Detroit, Mich., in 1793; entered the British army at the age of sixteen, and served against Napoleon I. He subsequently gained distinction in South Africa, India, Afghanistan, and the Crimea, and was made (1863) a full general in the army. He also became a grand officer of the Legion of Honor, colonel of the Forty-first Foot, etc.

England's Point, a post-office in Cherokee co., N. C., 18 miles from Murphey, the county-seat.

Eng'le (Frederick), a rear-admiral of the U. S. navy, was born in 1799 in Delaware co., Pa.; became in 1814 a midshipman, in 1825 a lieutenant, in 1841 a commander, and in the Mexican war commanded the Princeton, in which he rendered distinguished services during the blockade. In 1855 he was made a captain. During the civil war he commanded the Hartford for a time, but owing to advanced age was soon assigned to less difficult positions, and was for a time governor of the naval asylum. In 1866 he was appointed a rear-admiral and placed upon the retired list. Died at Philadelphia Feb. 12, 1868.

Eng'leman's Mills, a post-village of Dade co., Mo., 8 miles from Greenfield, the county-seat.

Eng'les (Joseph Patterson), D. D., a Presbyterian divine, was born at Philadelphia, Pa., Jan. 3, 1793, and graduated at the University of Pennsylvania in 1811. In 1813 he became co-master of the grammar-school of that institution, and was (1817–45) master of the Classical Institute, of which he was one of the founders. In 1845 he became publishing agent of the Presbyterian Board of Publication. He was the editor of an edition of the Greek Testament and the author of several volumes, mostly for the young. Died April 14, 1861.

Engles (William Morrison), D. D., was born in Philadelphia Oct. 12, 1797, and graduated at the University of Pennsylvania in 1815. In 1820 he became pastor of the Seventh Presbyterian church in Philadelphia, in 1834 editor of the "Presbyterian," and in 1863 president of the Presbyterian Board of Publication. Died Nov. 27, 1867. He was a man of marked ability and excellence. He published "Records of the Presbyterian Church," a "Bible Dictionary," and other works, chiefly devotional.

Eng'lewood, a post-village of Cook co., Ill., at the junction of the Michigan Southern, the Pittsburg Fort Wayne and Chicago, and the Chicago Rock Island and Pacific R. Rs., 7 miles S. of Chicago. It is the site of the county normal school, which has a fine building and is very successful. This school is designed strictly for the education of school-teachers; both sexes are admitted. The school has a normal department, a training-school, and a high-school department. The tuition is free for residents of the county, but others pay $30 a year for instruction.

Englewood, a post-township of Bergen co., N. J., on the Northern New Jersey R. R., 14 miles N. of New York. The village is near the Palisades of the Hudson River, and has one weekly newspaper, four churches, four hotels, and a bank. It is a thriving place, and many of its citizens do business in New York. The township has been organized since the U. S. census of 1870.

Englewood, a post-village of Robertson co., Tex., on the International R. R., 15 miles N. E. of Hearne.

Eng'lie Har'bor, a settlement in the N. part of Newfoundland, near the entrance to Canada Bay, which is 15 miles long and from 2 to 3 miles in breadth. The shores abound in good timber, marble, and limestone.

Eng'lish, the post-office name of the village of Hartford, in Sterling township, Crawford co., Ind., 8 miles N. W. of Leavenworth, which is on the Ohio River.

English, a township of Iowa co., Ia. Its post-office is at Millersburg, 18 miles S. of Marengo, the county-seat. Pop. 1627.

English, a township of Lucas co., Ia. Pop. 960.

English (Earl), U. S. N., born Feb. 18, 1834, at Burlington, N. J., entered the navy as a midshipman Feb. 25, 1840, became a passed midshipman in 1846, a lieutenant in 1855, a lieutenant-commander in 1862, a commander in 1866, a captain in 1871. He was in the engagement with the Barrier-forts at the entrance to the Canton River, China, in 1856, and during 1862 and 1863 commanded several vessels of the Gulf blockading squadron. In 1864 and 1865 he commanded the steamer Wyalusing of the North Atlantic blockading squadron, and participated, in Oct., 1864, in the capture of Plymouth, N. C. F. A. Parker, U. S. N.

English (George Bethune), an adventurer and author, was born at Cambridge, Mass., Mar. 7, 1787, and graduated at Harvard College in 1807. He studied law and was admitted to the bar, afterwards read divinity, was licensed to preach, and in 1813 published a work in favor of Judaism, which Edward Everett and others answered in 1814. He tried in vain to enter the army; became a newspaper editor, was for a time a resident of New Harmony, Robert Owen's community, and then became a lieutenant of U. S. marines. He went to Egypt, resigned his commission, became (according to some accounts) a Mohammedan, entered the Egyptian service, in which he gained distinction in 1820 in the expedition against the Mamelukes and hostile tribes of Nubia, serving as an officer of artillery. He afterwards became U. S. agent in the Levant. In 1827 he returned to the U. S., and went to Washington, D. C., where he died Sept. 20, 1828. He possessed a great readiness for the acquisition of languages, and was the author of several works, chiefly respecting religious questions, and a "Narrative of the Expedition to Dongola," etc. (1823). Mr. Everett accuses and convicts English of wholesale plagiarism, flagrant dishonesty in perverting the sense of quoted passages, and gross indelicacy and indecency of language and sentiment. He was a man of remarkable talents, but of reckless and inconstant character.

English (James E.), an American statesman, was born at New Haven, Conn., in Mar., 1812. He became a successful merchant and manufacturer, was a Democratic member of Congress (1861–65), and was elected governor of Connecticut in 1868 and 1870.

English (Thomas Dunn), M. D., an American poet and lawyer, born in Philadelphia June 29, 1819. He became in 1856 a medical practitioner near New York City. Among his works are several successful dramas, numerous novels, among them "Walter Woolfe" (1844), and a volume of poems (1855). Dr. English has won a high reputation as a humorist and critic, and has been long prominently connected with important journals.

English Centre, a post-village of Lycoming co., Pa., in Pine township, 20 miles N. W. of Cogan Station, which is on the Williamsport and Elmira R. R.

English Channel [Fr. *La Manche*, "the sleeve"], that portion of the Atlantic which separates England from France. It extends on the English side from Dover to Land's End, and on the French from Calais to the island of Ushant. On the E. it communicates with the German Ocean by the Strait of Dover, 21 miles wide, and on the W. it opens into the Atlantic by an entrance 100 miles wide. At its greatest width it is about 150 miles. On the English side, off the coast of Hampshire, lies the beautiful Isle of Wight. Guernsey, Jersey, and the other Channel Islands are situated off the N. coast of France. The Channel has a current that sets from the westward, and it is noted for its disagreeable roughness, which causes its passage to be dreaded by tourists. Portions of the Channel are of dangerous navigation, but chiefly near the shores. There are extensive and important fisheries both on the English and French coasts.

English Cove, a fishing-village of Conception Bay district, Newfoundland, 3 miles distant from Brigus.

English Harbor, in the island of Antigua, is one of the finest ports in the West Indies, and is capable of receiving vessels of the largest class. It has a dockyard and a naval hospital, and is perfectly secure in all winds. It is on the S. side of the island, in lat. 17° 3′ N., lon. 61° 45′ W.

English Harbor (West), a port of entry of Fortune Bay district, Newfoundland, has extensive cod and herring fisheries. Pop. 210.—There are several fishing-towns of Newfoundland called English Harbor, one of which, a post-village of Trinity district, 7 miles by road and ferry from Trinity, has a pop. of 350.—Another English Harbor is a small settlement on Greenspond Island, off the E. coast of Newfoundland.—English Harbor East is a settlement on the N. side of Fortune Bay, Newfoundland, near its head. Pop. about 100.

English Lake, a post-village of Starke co., Ind., at the outlet of English Lake, an expansion of the Kankakee River, and on the Columbus Chicago and Indiana Central R. R., 4 miles S. E. of La Crosse, Ind. It is in Jackson township.

English Language and Literature. The English language is the speech of the people and the descendants of the people who between A. D. 425 and 600 took possession of the greater part of the island before known as Britain. From the time of their settled possession of this country they and their language were called English, and their land was called England, at home and abroad. In later years, and for a long time, they have been called Anglo-Saxons, and their language Anglo-Saxon, but this compound name is fictitious, and was unknown to them. They were so called by historians because, according to the earliest accounts of their migration or conquest, at a time when migration meant conquest, they were chiefly composed of two tribes, the Angles and the Saxons, with whom, in smaller numbers, were another tribe called the Jutes, of whom little more is known than their name. These people came from a small tract of country about the union of the peninsula of Denmark with the mainland, which is now known as Sleswick-Holstein. They were an offshoot of that branch of the Indo-European, or Aryan, race known as the Teutonic family, which itself branched into three divisions—the Scandinavian, the Gothic, and the Teutonic proper. The Scandinavian went northward; its representatives are now the people of Norway, Sweden, Iceland, and Denmark. The Gothic branch was the southernmost. It has perished by absorption, and the only remnants of its language, which has been dead for nearly a thousand years, are a mutilated translation of the Gospels, a translation of St. Paul's Epistles, fragments of Esdras and Nehemiah, made by Bishop Ulfilas about A. D. 350, and a calendar. The main branch, the Teutonic proper, filled the country now somewhat vaguely known as Germany. The Germans, however, do not call themselves or their language German, but Deutsch, and this Deutsch people divided itself into two branches, the Hoch Deutsch, or "High German," and the Platt Deutsch, or "Low German." The people who went from what is now called Sleswick-Holstein to what, at the time of their going, was called Britain, belonged to the latter branch of the Teutonic stock. The English language is therefore, by origin and main affinity, a Platt-Deutsch tongue. Among living tongues it is nearest of kin to the Frisian, which is still spoken by a small people on the shore of the North Sea, on the borders of Holland nearest to Denmark. In the formation of the English language the kindred Norse or Scandinavian folk had a directly and an indirectly modifying influence, which shall be considered hereafter. The English, or "Anglo-Saxon," language must have been spoken in the country from which the Angles and the Saxons came, but no trace of it was left there; and chiefly because the emigration of the people to Britain was so complete that it left the country for a time bare and almost desolate. The English language, as it was taken into Britain by the men who were to supplant the Britons and to change the very name of the country, was simple and unmixed, so far as any language can be simple and unmixed; and it so remained for centuries. The Celtic dialect of the subdued Britons had no influence upon the sturdy speech of the Teutonic invaders, who ere long filled the whole island from the Grampians to the English Channel with their language as with themselves. And it should be here remarked that the language spoken from the Grampians southward was English, or "Anglo-Saxon," and that what is called Lowland Scotch owes none of its peculiarities to any Gaelic influences, but is as purely and absolutely English as the dialect spoken in any other part of the island; and, indeed, that what is sometimes called "broad Scotch" is probably more like the original speech of the Angles than that more cultivated and literary speech which has, by a certain right, arrogated to itself exclusively the name *English*.

The Early English, or "Anglo-Saxon," was a simple or homogeneous language; that is, its words were all, or as nearly as possible all, of one stock—the Platt-Deutsch branch of the Teutonic stock. It was also a synthetic or inflectional language; that is, it expressed time, condition, number, and person by changes in the forms of words, like the Latin and the Greek, and not by the use of "auxiliary" words. In this condition it remained in England for about six hundred years (A. D. 450 to 1066), changing somewhat, as all living or spoken languages change, and receiving very slight additions from the Celtic tongue of the Britons, and more considerable accessions from that of the Danes, who began their inroads about the end of the eighth century, and who at last distributed themselves over the northeastern part of the island, and even obtained control over it, under Cnut, for about fifty years. When they were driven out as a ruling power they left behind them, of course, many descendants, and also memorials of their presence in many words which had been taken into the language, and in many names of places. The termination *by*, as in Derby, Whitby, Naseby, Holdenby, etc., marks their presence. The terror and confusion consequent upon the ravages of the furious Danes helped to sweep away the little that there was of scholarship and literature among the English (or Anglo-Saxons); but even they were not too rude to escape the intellectual ruin which spread over Europe in the Dark Ages, and the light of their little learning was going out of its own feebleness when it was extinguished by an utterly barbarous violence.

Upon a country thus harried, distracted, and oppressed there came yet another change—that of the conquest by William of Normandy, A. D. 1066. The Normans took absolute possession of the island, over which they spread themselves, carrying with them their retainers, bringing with them their priests, and England became a Norman possession and colony; the speech of the conquerors becoming, consequently, that of the court, of courtly circles, and of all public documents and transactions. The Normans belonged to the Scandinavian branch of the Teutonic stock, which had spread northward, even to Iceland. Sailing southward, some of them had taken possession of a province of France, called from them Normandy; but these retained neither their Scandinavian tongue nor manners. They adopted those of the French whose land they had seized. Although they had been in Normandy only about two hundred years when William set out for his invasion of England, they then spoke a dialect which is known as Norman-French. For their day, they were an accomplished and an elegant people. The English (or Anglo-Saxon) tongue, being reduced to the position of a language spoken only by rude tillers of the soil and artisans at that dark period of the world's history, soon lost its distinctive forms and its nicer inflections; a process by which, although at the time deteriorating, it was prepared to become with greater ease an analytical language on its amalgamation with the Norman-French. Yet it never became in any sense French or Romanic, but remained in its essence and in its structure English.

The elements of our present composite English are therefore (1) pure English or "Anglo-Saxon," (2) British or Celtic, (3) Danish or Norse, (4) Norman-French, (5) Latin, (6) Greek, (7) words adopted from all languages, including Arabic, Hebrew, and even those of the savage aborigines of Africa and America. Words of the last class are comparatively few in number; their presence in the language does not at all affect it in its structural or historical aspect, nor do they in any way distinguish it from other Indo-European tongues.

1. Pure English, or Anglo-Saxon, which entered Britain about A. D. 450, and became the dominant tongue about A. D. 600, furnishes modern standard English with its strength, its stability, its vitality, and its real character. It is the distinctive element of our speech; and not only so, but it forms, except from a lexicographer's point of view, the bulk of the spoken language. If all other elements were taken away, the language would yet exist with its life and vigor unimpaired. We could live and love and hate and work and play and worship, and express all our wants and our feelings, tell tales and sing songs. But were this element to be removed, the language would fall to pieces in heterogeneous, disconnected, and lifeless masses. And yet in all copious dictionaries of the English language the words of other than purely English origin are quite three-fourths of the whole vocabulary. This seeming paradox is owing to the fact that all or almost all our words of commonest and most necessary use, including those particles which connect the others and modify their meaning, are pure English, while those which belong to literature, science, and art, which express abstract ideas and the subtle variations of thought, are, in the main, of foreign, and chiefly of Romanic, origin. The words which are used by all, men, women, and children, learned and unlearned, and used by all most often, belong to the former class: those which are used chiefly by the more or less learned classes, and much the greater number of them rarely even by those, belong to the latter. This is a phenomenon which appears in no other language, at least in anything like so great a degree. It makes modern English a two-sided, and, as we have words of both classes for many nearly identical thoughts and things, almost a double-faced language. The proportion of pure English used in literature is unavoidably different in the works of various writers and at various times. But although our speech has grown upon its Romanic side for centuries, and not at all of course upon its English side, on which it has rather dwindled, the proportion of the former element in use by a writer is not determined only by the period at which he lived: his taste, the character of his mind, his associations, and the nature of his subject, all influence his conscious, but generally his unconscious, choice of his medium of expression. Sir Thomas Browne and John Bunyan were contemporary, but they wrote almost in different languages; that of the

former being as nearly as possible Romanic, that of the latter as nearly as possible pure English.

The computations of Trench and of Marsh upon this subject are the most valuable and interesting that have been made. The former, supposing the English language of the present day to be divided into one hundred parts, apportions these parts, in round numbers, thus: Saxon, 60; Latin, including that which has come through the French, 30; Greek, 5; leaving 5, which he well says is perhaps too large a residue, to be divided among all other languages from which we have adopted isolated words. This estimate is founded upon such a vocabulary as that in Webster's or in Worcester's Dictionary, in which there are thousands of words, foreign in origin, which the general reader would not meet with once in his lifetime. Mr. Marsh found that in the vocabulary of the "Ormulum" (which was written about A. D. 1225)—that is, in the total of the several words used in it—97 per cent. of the words are Anglo-Saxon; that in the vocabulary of our English Bible 60 per cent. are native; that in that of Shakspeare the proportion is about the same; while in Milton's poetical works the home-born words are less than 33 per cent. But this computation tells us nothing of the comparative frequency with which words of English and of foreign origin are used. On an examination of various works of thirty representative authors who wrote between A. D. 1300 and the present day, and of four books of the New Testament, he found that Robert of Gloucester used 96 per cent. of English words; the author of "Piers Ploughman," in four entire divisions of his work, from 84 to 94 per cent.; Chaucer, in four tales, from 88 to 93 per cent.; the New Testament, represented by thirteen chapters from "John," "Matthew," "Luke," and "Romans," gave from 90 to 96 per cent., St. Paul's proportion being the smallest, St. John's the largest. Shakspeare, estimated by one act from each of three plays, gave from 88 to 91 per cent.; Milton, on a like computation, from 80 to 90 per cent.; Addison, 82 per cent.; Johnson, in the Preface to his Dictionary, sunk to 72 per cent.; and Gibbon, in one chapter of his History, to 70 per cent. of home-born words. From this level the writers of the present day are found to have risen in their use of the Teutonic element; Bryant using from 84 to 92 per cent.; Browning, 84 per cent.; Tennyson, 87 to 89 per cent.; Longfellow, 87 per cent.; and even Ruskin, critical writer on art although he is, from 73 to 84 per cent. of true English words. These are the most characteristic writers of the thirty well chosen by Mr. Marsh for examination upon this interesting point; for it is only by the consideration of such facts as those presented above that, seeing the pages of our dictionaries, and even the columns of our newspapers, so overwhelmed with words of Latin, French, and Greek origin, the reader who has not made a special study of language can rightly estimate the greatness and the strength of the native or Anglo-Saxon element in modern English. For example, Shakspeare and Milton use many stranger words but once, and many more but twice, but the home-born words hundreds, and in case of the particles thousands, of times; and a like usage is common with the best writers of the present day; yet *similar, conjunction,* and *domiciliary* each count one in a dictionary, as well as *like, and,* and *home.* The simpler and more direct a writer is, the more purely English will his language be, unless he writes upon philosophy, natural science, art, or literature. To paraphrase a well-known passage of Shakspeare's, homely brevity is the soul of our language—foreign tediousness its limbs and outward flourishes.

Notwithstanding what has just been said, we have now to remark that in the language of English-speaking peoples to-day the purely English part is so unlike that spoken by their forefathers before the Norman Conquest, who yet called their speech English and their country England, as to be, to all intents and purposes, a different language. The English of Alfred is far more unlike that of Victoria than the Greek of Homer is unlike the dialect now spoken in the Morea; although between the former there are only one thousand years, and between the latter more than three thousand, or about two thousand five hundred if we reckon from the redaction of the Homeric poems by Pisistratus. And yet the course of the language is distinctly traceable step by step; for in its remnants and records of early literature English is richer than any other tongue known to philology, Sanscrit being left out of consideration. The question has therefore arisen, What propriety is there in any distinction between English and Anglo-Saxon, and where shall the line of demarcation be drawn? It is urged by some philologists, and with much reason, that as a man is the same individual in infancy, youth, maturity, and old age, although no recognizable likeness could be found between the old man and the infant, so English is English under all the varieties of form which it has taken. How far this is true for what may be called practical purposes we shall now see in a brief examination of its structure in some of its earlier stages. For example:

"Đá ða hig férdon, đá comon sume ða weardas on ða ceastre, and cyđdon ðæra sacerda caldrum ealle ða þing ðe ðær gewordene wæron. Đá gesamnodon ða caldras hig and worhton gemót and sealdon ðam þegnum micel feoh, and cwædon, Secgeaþ ðæt hys leorning-cnihtas comon nihtes, and forstælon hyne, ða we slépon."

That passage is not to be understood by any reader, however intelligent and well instructed, who has not made a special study of the language in which it is written, although its meaning is familiar to almost every person, literate or illiterate. Only three words, *and, we,* and *hys,* would seem to him at all vernacular, and yet it was the every-day English of English people who lived in England. It is the Anglo-Saxon version of verses 11, 12, and 13 of Matthew, ch. xxviii., with our present version of which it would be well to compare it:

"Now when they were going, behold, some of the watch came into the city, and shewed unto the chief priests all the things that were done. And when they were assembled with the elders, and had taken counsel, they gave large money unto the soldiers, saying, Say ye his disciples came by night and stole him away while we slept."

Strange and foreign to us as the first passage is—as foreign as French or German—a brief examination of it will make clear to any person, although entirely unacquainted with Anglo-Saxon, that it is written in a tongue with the accents of which he is not entirely unfamiliar. *Férdon* is fared, went; *comon,* came; *sume,* some; *weardas,* wards, watch; *ceastre,* or caster, city (as in Lancaster); *cyđdon,* quoth, told; *sacerda,* priests (sacred persons); *caldrum,* elders; *ealle,* all; *wæron,* were; *worhton,* worked; *gemót,* a meeting; *sealdon,* sold, gave; *þegnum,* thanes; *micel,* mickle, much; *feoh,* fee, pay, money; *secgeaþ,* say; *leorning-cnihtas,* learning-knights, disciples; *nihtes,* nights; *forstælon,* stole; *hyne,* him; *slépon,* slept. It thus appears that almost all the words in this passage are essentially English now. In the lapse of eleven hundred years they have changed somewhat in form, and somewhat, but not essentially, in meaning. It will help us to understand the nature of the change which took place in the language if we compare with the foregoing another version of the passage—Wycliffe's—which, although from the Vulgate, is sufficiently correspondent to the others for our purpose:

"The whiche when thei hadden gon, loo, summe of the keperis camen into the cytee, and tolden to the princes of prestis alle thingis that weren don. And they gedrid to gidre with the eldere men, a counceil takun, ȝaue to the knyȝtis plentenous money, saying, Seie ȝe, for his disciplis camen by nyȝte and han stolen him, us slepinge."

Wycliffe or his co-workers made his translation about six hundred years after the first quoted above, and which was the first that was made into any form of English; in the making of which the Venerable Bede took part. This passage in the Wycliffite version gives us some notion of the nature and extent of the changes which had taken place during that period, for, although antiquated, it is unmistakably English—almost as easily understood by any intelligent person as if it had been written to-day, although it was written about five hundred years ago. But certain forms in it at once attract our attention. They are *hadden* (had), *camen* (came), *tolden* (told), *weren* (were), *han* (have). This ending in *en* is no rude or dialectical form of language. It will be found that the nominatives to all these verbs are plural. They are therefore plural forms of the verb which have been dropped since Wycliffe's day. They are a remnant of the elder form of the language; for, looking back to the earlier version, we find like plural terminations, but instead of *en* we find *on*—*férdon* (fared), *comon* (came), *wæron* (were), *worhton* (worked), etc. In the Wycliffe version we find also the plural forms *keperis, prestis, thingis, knyȝtis,* which since Wycliffe's day have passed into *keepers, priests, things,* and *knyghts.* In the earlier version we find a like syllabic plural in *s,* but instead of *is, as*—*weardas* (wards), *ealdras* (elders), *cnihtas* (knights). Besides the forms already remarked upon, we find in the earlier version *ealdrum,* meaning elders, as *ealdras* does, but elders in another relation, the same which is indicated by a like termination in *þegnum. Secgeaþ* is "say," but it is "say" imperatively. The old imperative therefore was in *th,* but this had begun to pass away five hundred years ago, for Wycliffe writes *seie* (say). Another form in the earlier version attracts our attention: *nihtes,* meaning by night, "comon nihtes;" "they came by night," as we say; but this *nihtes* is a genitive form, and means "of night;"* but so even now-

* The true genitive of *niht* is *nihte,* and *nihtes* has been regarded as an adverb. But it seems rather to have been conformed to *dæges. Dæges and nihtes* means, "of (or by) day and of (or by) night."

a-days, among some people, we hear such phrases as "He came o' nights." But the fashion of expressing this thought by a change in the word *niht* had passed away before Wycliffe's day, for he uses a preposition and writes "by night."

By this brief comparison of these passages we have a suggestive illustration, but nothing more, of the changes which the old English language underwent in the course of years, until, about A. D. 1525, it assumed substantially the form in which we have it now. Those changes may be succinctly said to have been the gradual disappearance of the case-endings of nouns, except the possessive, which was contracted from *es* to *'s*, and the nominative plural, which was changed from *as* to *es*, and in many words to simple *s*;* a like change, but complete in the adjective, which loses all distinction of the form and the sense of case and of number, and does not conform to or agree with its substantive; the entire disappearance of gender; the loss of the infinitive and imperative form of the verb, with the distinctions of person except in the third person singular; the only other inflectional changes remaining being those of the preterite and present or indefinite participle in the weak verbs (*love, loved, loving*), to which is added the perfect or definite participle in the strong verbs (*sing, singing, sang, sung*). The verb *to be* is not at variance with this assertion, its several tenses, and even persons, being taken from three distinct verbs; which appears to have been the case in the whole Indo-European family of speech, the Sanscrit included, from the earliest ages. Truly inflected case and personal endings are preserved only in the pronouns; and even there imperfectly or irregularly, for although *his* and *him* are inflectional forms of *he*, *me* and *mine* are not inflected forms of *I*, nor *us* and *ours* of *we*. Briefly, in this regard grammatical forms, with a few exceptions, disappeared, and with them the grammatical construction required or permitted by those forms.

The modern English sentence is built only upon the logical relation of thought, not upon the formal relations of words. Besides these changes there is another, that of contraction, a kind of phonetic degradation which is constantly going on more or less in all languages. Syllables are dropped or contracted, so that not only does *lufiath* become love, *maken*, make, *hlaford*, lord, and the like, but what used to be, only two hundred and fifty years ago, *work-ed* has for a long time been spoken and is now written by some persons *workt*. Letters are also dropped which do not affect the syllabic sound of the word, as *wou'd* and *shou'd*, for *would* and *should*, in which, within the memory of living men, old people used to pronounce the *l*. Language appears to shut up on itself like a telescope.

The next change in the English language in the order of time—one which, in fact, began long before that just sketched was completed—is the introduction of the Romanic element; that is, of words which came directly or indirectly from the Latin language. These words are of three sorts: First, those which came through the Norman-French, and which are ours by inheritance from the Normans who eight hundred years ago made England their home, and who in the course of two centuries became fused with the English people; of which *castle, faith, spy, person, poor, custom, sermon, voice, place*, and *rage* are examples. Secondly, words of general use formed by scholars in later years directly from the Latin, or from some one of the Romanic languages, or which have been adopted without modification from those languages; examples of the first sort under this class being *index, consul, circus, opera;* of the second, *trait, chagrin, portmanteau, puisne* or *puny*. Thirdly, words common to science in all languages, which have come into simple or metaphorical use in English by reason of the diffusion of knowledge and the immediate, every-day connection of science with the affairs of common life. Examples of this class are *zenith, diameter, tangent, ellipse, fulcrum*.

The Romanic or Latin elements of the English language have been divided into Latin of the First Period—that which is a mere trace of the Roman occupation of Britain, and which appears chiefly in the compound of *castra*, "a camp," in the names of places, as Lancaster, Doncaster, etc.; Latin of the Second Period—ecclesiastical terms consequent upon the conversion of the English or Anglo-Saxons to Christianity about A. D. 600; Latin of the Third Period—that large formative element which came in through the Norman-French; and Latin of the Fourth Period—all Romance words which have been brought in since the beginning of the sixteenth century. But for an understanding of the formation and growth of the language the division first set forth seems the better, as the Latin of the so-called first and second periods is very small in proportion, and has had a very little formative influence, while the Latin of the so-called fourth period includes the two very diverse elements (1) of Romanic words which have been really taken into the language and subjected to its formative influence; and (2) those which, originally little more than signs or technical names common to science or to the arts the world over, have been transferred into speech in a literal or a metaphorical sense. In tracing the history of our language the only Romanic element of high importance is that which is due chiefly to the presence of the Normans in England, and which became welded into English speech about A. D. 1350.

For about one hundred years after the Norman Conquest the conquerors and the conquered held themselves as much as possible aloof from each other—in scorn on the one side and sullenness on the other. And for nearly two centuries more the government of England, politically and ecclesiastically, was carried on in Latin and in Norman-French. These two languages prevailed in the court, in the universities, in Parliament, and in the courts of law: and even in the grammar-schools the boys construed their Latin into Norman-French. But as the Normans were few and politic, and the English were many and sturdy, there was unavoidably some mingling of the two languages as well as of the two peoples, and the English gradually prevailed. Political and patriotic motives, which cannot be here noticed in detail, combined with the natural influences already mentioned to turn Normans into Englishmen, both in feeling and in speech, until, about A. D. 1350, English took the place of Latin in the schools and in the courts of law, and the speech of the whole of the people of England became English. It was not, however, the English which the Norman invader heard at Hastings which obtained this compensating victory, but a speech much modified and largely mixed with strange elements. What has come down to us of that which was written in England during these three hundred years is worthless as literature. Words could hardly express its barrenness of thought and of feeling and the rudeness of its structure. But its worth in the history of the language cannot be overrated.

Before the Conquest there were two broad dialectic distinctions in English speech—the Northern and the Southern. The Northern dialect, showing the influence of the Angles and having a marked infusion of Norse, is known as the Anglian. It has left very few literary records of its existence; partly, it has been supposed, because of the destruction of the monasteries by the Danes. The Southern was more Saxonish, free from Danish mixture, a softer speech, more cultivated, and it left a literature which may almost be called copious. But the change to which living language is always subject, and which is greater and more rapid when the mass of the people can neither write nor read, and their speech is excluded from literature, from the court, and from public transactions, caused such modifications after the Conquest that in the thirteenth and fourteenth centuries three great dialects of English can be plainly distinguished—the Northern, the Midland, and the Southern. These differed from each other even more in their inflections and in their construction than in their vocabularies. It was not the Southern that prevailed and became standard English, or "the king's English," as it has been called, but the Midland, and this was modified more by influence from the North than from the South.

Of the English written between A. D. 1100 and 1350 that of hardly any two authors was alike. The language, having no recognized standard, was used by each scribe according to the mode of speech that prevailed among the people among whom he was bred and for whom he wrote. Writing was therefore as dialectical as speech, and owing to the immobility of the people and the lack of communication between them, a separation of fifty miles made a difference of dialect which is quite perceptible upon close comparison.

For the purposes of the present sketch it is unnecessary even to glance at more than the few most prominent and most significant of the English writings of this period. Layamon's "Brut" is a rhymed chronicle of the traditionary history of Britain. It was a translation, with large additions, from the Anglo-Norman poet Wace's "Brut d'Angleterre," itself a translation from the Latin of Geoffry of Monmouth, which professes, probably with truth, to be founded upon a British or so-called Welsh original.† Layamon's work was written about A. D. 1200. The dialect is the Southern, and is regarded by Sir Frederic Madden, whose authority is very high, as a fair representative of the language which prevailed among the more cultivated people

* The earliest English or "Anglo-Saxon" had various plural and genitive forms, which, for the sake of brevity and convenience, are here passed over.

† Welsh is not a national or folk name. It means merely "foreigner." The Teutones, Teutch, or Deutch, whom we call Germans, called foreigners Welsh, as the Greeks called them Barbarians.

throughout the south and west of England. It is marked by departures from the inflectional forms of Anglo-Saxon or pure English, and by a consequent disregard of the construction founded upon them, which shows that the original English was already broken down even in the South, where it held its own longest, and was far advanced in the transition to Modern English. Gender has almost disappeared; the imperative takes *to* before it; the government of prepositions is disregarded; strong verbs have sometimes weak preterites and participles; and *a* appears as an article. But although many Norse words are found in the "Brut," it is important to remark that the number of Norman-French words is very few indeed. Less than fifty are found in the whole poem (if so it must be called) of 32,250 lines. Considering that Layamon's work is a translation by a priest from a poem in the Norman-French, then spoken by the rulers of England, which was itself translated from the Latin, this is a very significant fact. It shows that the English, although it had broken up as to its forms, had yet kept itself almost entirely free from Romanic intermixture during one hundred and fifty years. The same interesting fact is established by a very important work, a metrical paraphrase of the Gospels, written about the same time by a monk named Orm or Ormin, and which was called by its author, from his own name, the "Ormulum." This specimen of Early English versification has a peculiar value in the history of the language, from the fact that the writer undertook to express the exact pronunciation of words by a system of spelling peculiar to himself. This was the indication of the short sound of a vowel by the doubling of the following consonant, while in the case of a long vowel the following consonant would be single, the effect being like that of the final *e* with us; as, for instance, *pin* and *pine*. Thus, Orm would write "thin" *thinn*, but "thine" *thin*, and "pan" *pann*, but "pane" *pan*, "own" *onn*, but "on" *onn*. He writes for example

"Nu brotherr Wallterr, brotherr min."

and

"Þe Goddspell unnderrstanndenn."

Thus early was the first attempt at phonographic English spelling. The means taken was an application of a rule which has prevailed always more or less even to the present day, only that we call in the final *e* or accept its aid. For example, *pull, pule, tall, tale, mall, male, pill, pile, till, tile, tiller, tiling, fill, file, filler, filing.* This phonographic freak of Orm's, together with the rhythm of his verse (unfortunately, he did not use rhyme), gives a very clear notion of the pronunciation of English as he spoke it; and considering the remote period at which he lived, and the unfixed state of the language then, it is remarkable how small and few comparatively have been the changes in the sound and accent of English words. Orm's dialect is East Anglian; the infusion of Norse words in his vocabulary is very strong; and altogether his work is a characteristic representative of the Northern form of English about the beginning of the thirteenth century. Like Layamon's "Brut," it is notably free from any intermixture of Norman-French. Considering these points, it is very remarkable that the "Ormulum" is, of all important writings of its period, the most like modern English; a fact which indicates the very strong influence which the Northern dialects exerted in the formation of our standard English speech.

We have thus far had "English undefiled" under our consideration, but we have now reached a period at which a flood of French or Romanic words was turned into that "pure well." The interfusion of the languages was the consequence and the sign of an interfusion of the people. Englishmen did not become Normans—that was impossible—but the Normans became Englishmen—Englishmen of a high and haughty class, a noble order, but still Englishmen; and taking for their own use the language of the people whose country they had also taken for their own use, they brought a large and in most respects a valuable store of words from the speech of their race as their contribution to the common stock. The introduction of French words was largely due, there can be no doubt, to the influence of the priests. These men were dependent upon the Norman nobles; they were their beneficiaries, their chaplains. The higher members of the priesthood, and a very large proportion of the whole order, were of Norman race. Their professional language was Latin, of which Norman-French was a dialect. Their intercourse with women and children, and the reverence in which they were held by them, weak and plastic, but still the makers and the stuff of future Englishmen, gave them an influence upon the language of the country which can hardly be overrated. What sort of English the priests began to use about this period is shown by the "Ancren Riwle," a treatise on monastic life which was written by a priest for the guidance of three ladies about A. D. 1220. Intended for private use, it so commended itself by its matter and style to general favor that it soon became widely diffused, and there are in existence several copies of it, no two of which, however, are exactly alike, and some of which differ greatly from the original. The difference, however, is chiefly, if not altogether, dialectical. This little work is of interest enough in both a literary and a linguistic point of view to make a brief passage worthy of our consideration. The following description of the glutton is picturesque and humorous:

"Þe ȝuire glutun is þes feondes manciple. Uor he stikeð euer iðe celere, oðer iðe kuchene. His heorte is iðe disches; his þouht is iðe neppe; his lif iðe tunne; his soule iðe crocke. Kumeð forð biuoren his Louerde besmitted and bismeoruwed, a dischs ine his one hand and a scoale in his oðer; maðeled mid wordes, and wigleð ase uordrunken mon þet haueð imunt to uallen; bohalt his greate wombe, and te ueond laugweð þet he to bersteð;"—which being modernized is as follows:

"The greedy glutton is the fiend's manciple [purveyor]. For he sticketh either in the cellar or in the kitchen. His heart is in the dishes; his thought is on the nap [napery, table-cloth]; his life in the tun; his soule in the crock [pitcher]. He cometh forth before his Lord besmutted and besmeared, a dish in his one hand and a bowl in his other. He babbleth with words, and wiggleth as a fordrunken man that haveth a mind to fall, beholds his great womb, and the fiend laugheth that he to-bursteth."

The modern air of this not exceptional passage is remarkable. As far as the structure of the sentence is involved, it might almost have been written to-day. And as to the words, only a few of them have dropped out of use, and a few of them have changed a little in signification—none of them at all essentially. The same facts are not less apparent in the following passage, which is given first in the dialect of Dorsetshire, in which the "Ancren Riwle" is supposed to have been originally written; next, for the sake of a comparison of the variations, in that of Salop, to which the copyist was plainly accustomed:

"Ancre ne schal nout forwurðen scolmeistre, ne turnen
Ancre ne schal nawt for-wurðe scolemeister, ne turnen
An anchoress shall not become a schoolmaster, nor turn
hire ancre hus to childrene scole. . . . Hwon ȝe

bute þet leste þet heo mei, er þen heo kume hom.
bute þ leaste þ ho mei, ear þen ho ham cume.
but the least that she may before that she come home."

But perhaps the most important fact in regard to the "Ancren Riwle," a fact very important when considered with the other facts of the modern structure of its sentences, and its having been originally written in English (for most of the writings of this period are translations from the Norman-French), is that the number of words of the latter origin in it is three times as great, for instance, as that in Layamon's "Brut," the date of which is at most only about twenty years earlier. Its editor suggested that as it was written by a churchman for the guidance of ladies of the higher classes in conventual life, the number of Romanic words in it might be due to its ecclesiastical character. This, however, I find not to be the case. The number of such words in the whole work is 496, and a division of them into classes gives only 75 as of ecclesiastical origin or meaning, and 421 of such as may be regarded as referring to the affairs of common life. The proportion is therefore more than six and one half of the latter to one of the former.

The "Ancren Riwle" merits the exceptional consideration which it has received at our hands, because of its being an original English composition—a very rare thing at this period of our literature—and because it is in prose, to which poetry is in almost every way inferior in the study of language; poets, whether mere dull rhyming chroniclers or men gifted with the "faculty divine," being ever ready to use old words or new, and to take any liberty with form, sense, or construction, for the sake of rhythm, rhyme, picturesqueness, or impressiveness, if in any way they may be understood.

But although the "Romance of Kyng Alisaunder" and Robert of Gloucester's "Chronicle" are in verse, and translations, the first from the Norman-French, and the second from the Latin, these may be taken with some allowance as fairly indicative of the state of the language among the more cultivated speakers at the time of their production, which was about A. D. 1300. They both show that toward the end of this century Norman-French was shooting its bright glancing threads across the sturdy warp of English speech so freely as to change manifestly its tone and texture. The number of Norman-French words used in "Kyng Alisaunder" is 1140, that in Robert of Gloucester 853; and in both works these Romanic words are of all sorts and of all shades of meaning. And now we find an increase of the words compounded from the two languages, showing that the two-blooded English people were now welding them together, and that they were exercising upon each other a reciprocal if not a mutual influence.

Our attention has thus far been chiefly given to writings of southern English origin. But as we near the birth-time of modern English we are brought to face the fact that our language, as it has been written and spoken for five hundred years by standard authors and in the most cultivated society, is not a representative of the Southern dialect, although that dialect was spoken in London and in the counties south of the Thames and somewhat north of it. It was not at the king of England's court that the king's English had its origin. The earliest representative of English essentially modern in substance, form, and structure is found in the "Handlyng Synne," written by Robert Manning of Brunne or Bourne, in Lincolnshire, about A. D. 1305, it having been begun in 1303. The "Handlyng Synne" is a translation in rhyming verse of a Norman-French poem written about thirty years before. But it is not to the influence of its original that we owe the flood of Romanic words which pours through it, and in which respect it surpasses all previous known English writings, even "Kyng Alisaunder" and the "Ancren Riwle." There are not many lines, comparatively speaking, that do not contain a Romanic word; and as many contain two or even three, it may be said to have one at least for every line. About one-third of the writer's nouns, adjectives, and adverbs are Norman-French or of Latin derivation, which is, roughly speaking, about the proportion in good English of the present day. But not only have we to remark Robert Manning's use in the "Handlyng Synne" of this large proportion of French words, but that, of the consequently smaller proportion of Teutonic words used by him, a very considerable proportion were soon to pass out of sight and hearing. Another work of Manning's, a translation of Peter de Langtoft's rhyming chronicle of England, is also marked with these traits of language, but the infusion of Norman-French is not quite so great. He tells us in that work that he undertook it, and also we may be sure the "Handlyng Synne," for the good of what might be called "the average Englishman" of his day, and thus gives us reason to believe that it represents, nearly at least, that day's average English. He asks his hearers or readers to listen to

> "All þe story of Inglande,
> Als Robert Mannyng wryten it fand,
> & on Inglysch has it schewed,
> Not for the lerid bot for þe lewed,
> For tho that in this land wonn,
> Þat þe Latyn no Frankys conn."

The "lewd" were the ignorant, the un-"lerid," the commonalty. Let us, then, examine a passage written by an author who addressed himself in the first quarter of the fourteenth century to the generality of his countrymen, and to those who were ignorant of both French and Latin. The following lines are Manning's version, in the "Handlyng Synne," of St. Paul's description of charity—a description, like his definition of faith, never surpassed or to be surpassed:

> "Þoghe y speke as weyl wyþ tung
> As any man or aungel haþ song,
> And y lyve nat wyþ charyte
> No þyng avayleþ hyt to me.
> For y do þan ryght as þe bras
> And as þe tympan þat bete was;
> Þe bras to oþer gyveþ grete sowu,
> And bet hym self up and down.
> And þoghe y speke al yn prepheeye
> And have þe kunnyng of every maystrye,
> And wyþ gode beleve myghte seye
> Þe hylles to turne yn to þe valeye,
> Gyf hyt ne be wyþ charyte wroghte
> Elles he seyþ þat y am noghte.
> Þogh y gyve alle my worldes gode
> Unto pore mennys fode,
> And gyve my body for to brenne
> Opunly oþer men to kenne,
> But gyf thar be charyte wyþ alle
> My mede þarfore shal be ful smalle."

This passage no modern reader, who will attend to the sound rather than to the spelling of the words, and who will remember that þ expresses exactly what we express imperfectly by *th*, and that ȝ is the sign of a guttural sound between those of *g* and *y*, can have the slightest difficulty in understanding. He will rather be struck by its conformity to the established version—a conformity the more remarkable because even Wycliffe's translation had not yet been made. Manning's language, indeed, is, to all intents and purposes, modern English, spelling being an altogether unessential part of speech, and what is called the orthography of our day being in great part a conventional use of letters imposed upon us by pedants and printers. In Robert of Brunne we find the verb-change established which gave us, for example, "he *loves*" for "he *loveth*;" and he brings down the Northern *scho* (she) in place of *hi*, and uses þey (they) and þer (their) instead of *hi* or *hei* and *hire* or *heore*. He gives us the present or indefinite participle both in the Southern *ing*-form and in the East Midland in *and* (*synging*, *syngand*). For *loren*, the old past participle of *leosan* (to lose), and which we still preserve in composition, *forlorn*, he uses *lost;* and (still more strange to English of the day then but little past) for *thu lust*, the second person singular of the preterite, he has "þou lostest." Even now we preserve the old gerundial infinitive and say "you are to blame" and "this house to let;" but Manning, as if anticipating the squeamishness of people who generally can neither speak nor understand idiomatic English, wrote "þey beþ (are) *to be blamed*." We find in his "Handlyng Synne" very early, if not the earliest, examples of these phrases: *somebody, some one, one of these days, oftentime, heretofore, inasmuch, as well as, once forever, to and fro, thereunto, would God that! side by side, body and bone, all to pieces, do to death.* He uses a participle, and a French participle at that, for an English preposition, "*passing* all things," for "before all things." And whereas earlier writers had given foreign words English endings, as he did in writing *felunlyche* (felon-like), he gave an English word a foreign ending, translating the French *viteinage* by adding the Romanic *age* to the English *bond*, thus giving us *bondage*, and setting an example of composition which since his time has been continuously followed.

The man who wrote this English was born a few miles

from the extreme southern angle of Lincolnshire (the most northern of the midland counties), just where it borders upon the shires of Rutland, Northampton, and Cambridge. Manning was born and bred and lived all his life in Lincolnshire, and we may be therefore sure that we have in his writing the common speech of that county, and particularly that of its southern part. And there it was, one hundred miles (like five hundred now) from the king and his court, that the English of after courtly life and of literature took form. It was the speech of the rural Midland Englishmen, strongly influenced by the Anglian speech of the North, and much by the Norse invaders, tempered by the softer dialect of the South, that gave us the language which from the time of Chaucer to the present day has been the vehicle of a literature without an equal except that of the tongue of Homer and of Plato. The evidence of this philological deduction remains also in the speech of the peasantry of the country thereabout. The learned Latham has remarked: "The particular district where the difference between the language of the educated portion of the community and the masses is at its minimum, I believe to be the parts between St. Neots in Huntingdonshire and Stamford on the borders of Lincoln, Rutland, and Northamptonshire." And it must be always remembered that, using again his words, "it is the literature that resembles the dialects, rather than the dialects that emulate the literature."

The new English language was now fully formed. The changes which it afterward underwent did not appreciably affect its structure; and as to its substance, that was changed only by such loss and gain as in some degree must be wrought in all living speech. The language was in its structure and in all its vital substance Teutonic; it was English or "Anglo-Saxon." But amalgamated with it by centuries of contact and of friction was a mass of Norman-French or Romanic words, which, except from the narrowest and most bigoted Anglo-Saxon point of view, must be regarded as a part of the native English language. For the words were not adopted from another language, but two peoples having mingled their blood, they mingled their speech also; they who furnished the fewer numbers furnishing only a like proportion to the language. All Romanic words which are found in English writings (not Norman-French written in England) before A. D. 1350 seem to have justly a birthright in our modern English uninflected speech.

Although the English language was formed, there was yet no English literature worthy of the name, no writing which deserves to be read for its intrinsic merits. One author soon appeared who is worthy of notice because of the wide circulation of his book, which was due on the one hand to its subject, and on the other, we may be sure, to the fact that its style made it easily understood by all the people of England who were educated and intelligent enough to take an interest in any book. This book was Sir John Mandeville's "Travels," written first in Latin, then by the author in French, and last in English. It has no national character whatever, nor indeed any individual character derived from the mental traits or temperament of its author. Its interest to his contemporaries consisted only in its marvellous relations: to posterity its value is purely philological, and chiefly in its evidence of the copious admixture of Romance words which at the time when it was produced, soon after 1350, prevailed in the speech of English people. The story of this prose-writer, telling bare facts in bald language, contains a larger proportion of Romanic words than is found in the works of any poet of his century. Marsh supposes, with reason, that Mandeville used about fourteen hundred Romanic words not known in the previous century, and that between A. D. 1300 and 1350 as many Latin and French words were introduced into the English language as there were in the whole period of nearly two centuries and a half between A. D. 1066 and 1300.

Standing between the old English and the new, uniting the form of the one to the spirit of the other, is the author of "Visio Willelmi de Petro le Plowman," usually called "Piers Ploughman," an anonymous work of which there is reason to believe that the author was William Langland, Longland, or Langley, a clerk or churchman of some grade, who was born at Cherbury Mortimer in Shropshire. "The Vision of Piers Ploughman," to which the author or some other writer thoroughly imbued with his spirit afterwards added "The Creed," is a satirical poem written in the alliterative verse which was common to the Anglo-Saxon and Danish bards. This alliterative verse is without rhyme, and is dependent for its formal charm upon rhythm and the regular recurrence of words beginning with the same letter. The first of two verses, or the first part of a verse—that before the cesural pause—must contain two accented syllables, and the second, one, having the same initial sound. At the time when "Piers Ploughman" was written, about A. D. 1365, this verse was quite out of fashion among courtly rhymers, but we may be sure that it was familiar in ballads and folk-songs to the common people, to whom this poem was addressed and in whose interest it was written. It is remarkable that such being the purpose of the writer, and that his success being exceptionally great, the proportion of Norman-French or Romanic words used by him was not less than that found in the works of any of his immediate predecessors—evidence unmistakable of a thorough interfusion of the two tongues in common speech at or before the middle of the fourteenth century. The "Vision and the Creed of Piers Ploughman" together form a great national work, the first great original work in English literature. Neither the Vision nor the Creed has much coherence of plan, but the latter has more than the former. The writer was a humane satirist, and his purpose was to set forth the wrongs of his humbler countrymen suffered at the hands of nobles and priests and lawyers, but chiefly at those of the priesthood. He gave voice to the sorrow, the shame, and the subdued indignation of a deceived, oppressed, and pillaged people. The tiller of the soil from whose labors nearly all wealth springs, and who then, as often since, starved amid the food that he raised for others, found in him an advocate, and the grasping noble and the corrupt churchman a just judge and a pitiless satirist. The pathos and the humor of his work are not less remarkable than its causticity. It is in these respects, as in all others, thoroughly English in its tone and character; and as an exposition of popular feeling, and no less a picture of contemporary manners, it has not a superior in the whole range of literature. The following brief passages are characteristic of the author's style and of his subject-matter:*

"And thanne cam Coveitise · kan I hym naght discryve,
So hungrily and holwe · sire Hervey hym loked.
He was bitel-browed · and babber-lipped also,
With two blered eighen · as a blynd hagge;
And as a lethern purs · lolled hise chekes
Wel sidder than his chyn · thei cheveled for elde;
And as a bondman of his bacon · his berd was bi-draveled,
With an hood on his heed · a lousy hat above
And in a tawny tabard · of twelve wynter age,
Al so torn and baudy · and ful of lys crepyng
But if that a lous couthe · han lopen the bettre,
She sholde noght han walked on that welthe · so was it thred-bare." *Vision*, Passus v.

"And as I wente by the way · wepynge for sorowe
I seigh a sely man me by · opon the plough hongen.
His cote was of a cloute · that cary was y-called;
His hod was ful of holes · and his heare oute
With his knoppede shon · clouted ful thykke;
His ton toteden out · as he the lond tredede;
His hosen over-hongen his hok-shynes · on everiche a syde
Al beslomered in fen · as he the plow folowed.
Tweye myteynes as meter · maad al of cloutes,
The fyngres weren for-werd · and ful of fen honged.
This wit wascled in the feen · almost to the ancle
Foure sotheren hym byforne · that feble were worthi:
Men mighte reknen ich a ryb · so senful they weren.
His wiif walked hym with · with a long gode,
In a cuttede cote · cutted ful heyghe,
Wrapped in a wynwe shete · to weren her fro wederes
Bar-fot on the bare iis · that the blod folwede.
And at the londes ende lyth · a little crom-bolle,
And thereon lay a lytel chylde · lapped in cloutes
And tweyne of tweie yeres olde · opon another syde
And al they songen o songe · that sorwe was to heren;
They crieden alle o cry · a kareful note
The sely man sighed sore · and seyde, Children, beth stille."
The Creed, etc.

It is worthy of remark that the first great work in English literature was written in a language formed neither by scholars nor courtiers, but by the people at large, and that it was a protest against wrong, against fraud, against priestcraft and hypocrisy—a demand for the recognition of human rights, for personal freedom and liberty of conscience.

The "Vision," and more particularly the "Creed," of Piers Ploughman bear the stamp of a great historical period. At the time of their production John Wycliffe and his followers were disturbing the established religion of England at its very foundations, and the author or authors of "Piers Ploughman," if not openly attached to the Lollard party, must be reckoned as of it. As regards the "Creed," this fact was recognized in the most emphatic

* As these passages are quoted for their matter, and not for their language, I have chosen the text edited by Wright, and with him have modernized the þ and the ȝ, in preference to following the more accurate but less generally readable text of Skeat.

manner by the ministers of the prevailing religion, for they caused the copies of it to be so thoroughly destroyed that, whereas the old manuscripts of the "Vision" are many, of the "Creed" not one is known to exist. "Piers Ploughman," itself equally valuable as a record of the condition of language and religion, was thus one of the writings that ushered in that great work, itself equally important as to religion and language, the Wycliffite translation of the Bible. This was made from the Latin Vulgate by Wycliffe and some of his followers about A. D. 1380. No other single work ever exercised so much influence upon the political, moral, literary, and linguistic future of a people as the Wycliffite Bible did, except perhaps Luther's translation of the same Scriptures into High German nearly two hundred years afterward. It was the beginning of a revolution which freed Englishmen from the rule of a foreign hierarchy, and ended in the deposition of the Stuarts and in the Bill of Rights. Although it added little to the English vocabulary, it enriched English expression—we might almost say English idiom—with a strong and peculiar phraseology which sprang from the contact between Hebraic thought and English speech, and which, having been preserved through three hundred years, even to the revised translation of 1611, and having been read and listened to and taken to heart by so many generations of Englishmen, came to affect in a measure the whole popular cast of thought and of speech. . It was the Wycliffite version that did this; for although there was, as we have seen, an Anglo-Saxon version of the Bible, this did not spread among the English people, and being almost forgotten and quite incomprehensible to the English people at the middle of the fourteenth century, there was no such connection between it and the Wycliffite version as there was between the latter and the received translation: in fact, there was no connection at all. This translation, completed about A. D. 1380, was revised by John Purvey, a learned Wycliffite writer who had made the subject of translation a profound study, and who sought to render this version more exact and more conformed to English idiom, which end he attained with admirable skill, finishing his work about A. D. 1390. Apart from the peculiar Anglo-Hebraic phraseology before mentioned, this translation tended to modernize the language. It was, as to simplicity of forms of words and the untrammelled construction of the sentence, in advance of the general English writing of its day; and its unparalleled literary influence led to the confirmation of this freedom from grammatical restraint among all English people, particularly those of the middle and lower classes. This could be illustrated only by the examination of very much longer passages than it would be possible to quote within the limits of such an article as this; and it may now be added that having brought our sketch down to the appearance of modern English, we must hereafter concern ourselves rather with literature than with language, rather with the writers than with their materials. The need fits the occasion; for whereas before the production of "Piers Ploughman" the language was all and the literature was naught, we now see rising, in Geoffrey Chaucer, the day-star of English literature—not only a herald of the morn, but one whose bright rays have been neither dimmed nor eclipsed in the lapse of five centuries. Chaucer was a younger contemporary of the author or authors of "Piers Ploughman," having been born A. D. 1328, and having died about A. D. 1400. He was connected with the court, having married the sister-in-law of John of Gaunt, the father of Henry IV. He was pensioned, employed in diplomacy, and made comptroller of the customs. As Langland's poems were addressed to the middle and lower classes, and written in their interest, so Chaucer wrote for the nobles and gentry; and the tone of his poems was suited to the temper of his audience.

Chaucer was a voluminous writer, but his chief works are "The Canterbury Tales," "Troilus and Creseide," "The Romaunt of the Rose," and of his minor poems, "The Flower and the Leaf." Of these the "Canterbury Tales" are the most original and the most characteristic of his genius, although "Troilus and Creseide" is as fine a narrative poem, not of the heroic cast, as exists in any literature. Chaucer is essentially a narrative poet. He is the earliest poet since the revival of literature after the Dark Ages who has awakened an enduring sympathy in the characters and the feelings and the fate of his personages. He is the first, indeed, who portrayed real individuality of character. Each one of the personages in the pilgrimage to Canterbury, which is the occasion of the "Tales," exists to this day in the minds of his readers as a living character that has as real and independent a being as any creature of flesh and blood that we meet in our daily lives. In this respect he is a rival of Scott (in his novels), and almost of Shakspeare. Like the former, he paints them; like the latter, he makes them unconsciously paint themselves. He is English in all the traits of his mind and his style; and in nothing more so than in his humor. So early (also in "Piers Ploughman") did this peculiar trait of English literature, in which it is unrivalled by that of any other people, appear, and with all its inexpressible and humanizing charms in fullest bloom and subtlest fragrance. As an historical picture of the time in which they were written, the "Canterbury Tales" are as if the veil of five centuries were lifted and we looked in upon a gathering of our forefathers in the free enjoyment of each other's society. But above all Chaucer's other charms is that of his strong and clear imagination. What he described he saw in his mind's eye as clearly as if it appeared before him in the body. We see with him the very personal traits and tricks of the people that he sets before us, no less than the adventures through which they pass or which they relate. There is all the freshest charm of nature in him, joined with the elegance of an accomplished man of the world. So in his language there lingers some of the homely roughness of Early English, while at the same time it is strongly marked with the dainty splendor of the speech that, like some other pretenders, came over with the Conqueror. But he was not remarkable for an excessive or an unusual addiction to the new Romanic vocabulary. Spenser having applied to him, with more felicity of expression than truth, the phrase "well of English undefiled," he was for that reason, and because of his antiquity, accepted, even by those whose intelligence and knowledge should have taught them better, as the greatest exemplar of pure English—whatever that may be; so ready are men to adopt a compact phrase which saves them the trouble of thinking, and which, although full of emptiness, seems to be full of meaning. But it having been discovered that his lines are heavily charged with Romanic words, he was next regarded by Anglican purists as the chief defiler of English. And now that view also has been found, as we have seen, to be entirely unjustified by fact. The truth is, that the phrase in question is a perfect example of those utterly meaningless and worthless fine sayings which obtain acquiescence and currency because of their seeming sententiousness and the high authority of their origin. Chaucer's language was merely that of his time, and, like all really great imaginative writers, he concerned himself much with the ideas of men and things that he wished to present, and little with that of the admissibility of the words in which he presented them. The chief peculiarities of his language, upon which the rhythm of his verse much depends, are the retaining of the old plural in *en*, the infinitive of the same termination, the possessive in *es*, the imperative in *eth*, and the lightly-sounded final *e*, without which a large proportion of his verse is mere prose. Chaucer stands alone, not only in his merits, but in his literary position. He had no fellows; few contemporaries worth mentioning; and after his period "the blanket of the dark" fell upon our literature, through which peeped a few dim and struggling lights whose only function was to make darkness visible.

John Gower, a barrister, born about A. D. 1320, was the chief of Chaucer's contemporaries. His reputation during his life was great. Chaucer himself speaks of him with deference, and calls him the "moral Gower." But the dull, dead weight of his style has sunk him out of sight, and left only his name floating upon oblivion. His "Confessio Amantis," or "Confession of the Lover," is a long nondescript poem, to read which through requires the patient, self-sacrificing courage of a conscientious investigator of the history of our older literature. It has little claim to attention even as a contemporary record of manners and morals.

Of all the poets of Chaucer's day, and even of the fifteenth century, which he ushered in, John Barbour was the only one worthy even of comparison with him. Barbour was, according to the political division of the country, a Scotchman. But political divisions have nothing to do with literature or with language, and Barbour merely wrote in Northern English as Chaucer wrote in Southern. Barbour and his neighbors called their language, and rightly called it, English, and so it continued to be called until toward the end of the sixteenth century, when local pride and political jealousy caused it to be called Scotch—a change of designation which has been the cause of much misapprehension and confusion. Nothing more truly English in speech or in spirit was ever written than this passage from Barbour's principal work—a long epic, or at least historical narrative poem, "The Bruce":

"Ah! Freedome is a noble thing
Fredome mayss man to haiff liking
Fredome all solace to man giffis
He levys at ess that frely levys.
A noble hart may haiff nane ess.
Na ellys nocht that may him pless.
Gyff fredome failyhe: for fre liking

Is yharnyt our all othir thyng.
Na he that ay hass levyt fre
May nocht knaw well the propyrte,
The anger na the wretchyt dome
That is cowplyt to foule thyrldome.
But gyff he had assayit it
That all perquer he suld it wyt;
And suld think fredome mar to pryss
Than all the gold in warld that is."

Book I., ll. 225–240.

The seeming difference between the language of this passage and that of the same passage written by Chaucer or one of his neighbors is little more than a difference of spelling, indicative, in some cases, of a difference, unessential, of pronunciation. For instance, the strangest-looking word, *yharnyt*, is merely our *yearned*, pronounced almost exactly as it was pronounced by our own grandfathers. Barbour had not Chaucer's imagination, his delicate portrait-painting touch, his wit, or his humor, but he was a lively narrator and a strong and earnest thinker. Many passages of his poem show him to have been the possessor of true epic power. His language in all essential points shows a rapid passing away of even the traces of the old English. He preserves the present participle in *and* indeed, *com-and*, *pleas-and*, *purches-and*, but the final *e* counts for nothing with him; and although he often uses the old Saxon *swa*, it becomes *sa*, on its way to *so*, within a few verses.

No less remarkable than the sudden uprising of such a poet as Chaucer, and we may even say of Barbour, is the fact that within their century there came no writers of either poetry or prose who were worthy of being called their followers. For nearly two hundred years after the death of Chaucer the darkness which we have already mentioned fell upon the English mind. For this there were two reasons that we can now see; perhaps others hidden from us by the distance of time. The first is the violent repression of all free thought which was brought about by the efforts of the Church to crush Lollardism and extinguish the very embers and sparks of the fire kindled by the Wycliffites; next the desolating War of the Roses, which broke out A. D. 1455, and desolated England with civil war and its consequences for quite half a century, although the war itself lasted but thirty years. Of the anti-Wycliffite writers the most eminent was Bishop Pecocke, who had some vivacity of style if no strength of thought. The most remarkable prose-book of the latter part of the fifteenth century is Sir Thomas Mallory's "Morte d'Arthur," compiled and translated from the French about A. D. 1470—a work which in its animation, and sometimes its simplicity and tenderness of style, does something to relieve the literary barrenness of its century. Mallory's language is remarkable for its freedom from Romanic words, to which fact it owes much of its directness and its strength.

At this period printing was introduced into England by Caxton, who printed his first book, "The Game and Playe of the Chesse," in 1474. Caxton was a translator and an adapter as well as a printer, but not even his wonderful mechanical art had at first much influence upon either literature or language. Of poets, or writers of rhyming verse, in this period we have Occleve (about 1370–1454) and Lydgate (about 1370–1450), whose names only need be mentioned in a sketch like this.

It was in the North that the best literary work was done at this period, although Andrew of Wyntoun, a clerical chronicler in verse who flourished about the beginning of the fifteenth century, is little more than a rude rhymester, the value of whose work is chiefly historical. But James I. of Scotland, in his "King's Quair," shows fancy, fine conceit, and the fruit of a careful study of Chaucer, whose works soon began to exercise a great influence upon our poetical literature. Robert Henryson (or Henderson) not only studied and imitated him, but wrote a continuation of "Troilus and Creseide," which he called "The Testament of Fair Creseide," which has been with some reason deemed not unworthy of being printed in company with Chaucer's poem. Of all the extreme Northern English poets, Henryson and James I. show most the influence of the Southern language and literature. Henryson, who lived until about A. D. 1500, is the author of other poems of merit, among them the beautiful pastoral "Robin and Makeyne," which was reprinted in the Percy Collection. A poet known as Henry the Minstrel, or Blind Harry, composed a long poem of which the life of William Wallace was the theme. It is a genuine strong piece of poetical "making," quite Homeric in a rude and humble way and full of hatred of "the Saxon;" Blind Harry himself being probably as good a Saxon or "Anglo-Saxon" as there was to be found south of the Tweed. After this period the so-called Scots literature shows a wider divergence in spirit and in form from that of the South, or of England proper.

The first part of the sixteenth century produced in Sir Thomas More, King Henry VIII.'s second lord chancellor, the first English prose-writer of merit after Chaucer, whose prose, although not equal to his poetry, was, like that, the best of its kind that England saw for more than a century. More was a man of learning for his time, wise, humorous, penetrative, and of noble impulse and purpose. He wrote many controversial works of timely interest, and in Latin his famous "Utopia." Of his English writings the most important is his "Life and Reign of Edward V." (called his "Life of Richard III."). In this his narrative power and his characterization of the personages whom he sets before us give him a conspicuous as well as an early place in the true historical English literature. His writings were produced between about A. D. 1515 and 1535, when he was beheaded. About the same time was written Sir Thomas Elyot's political work, "The Governour." It was theology, however, which now again gave new life to English literature, upon which William Tyndal and his followers conferred a benefit only inferior in degree to that which they bestowed upon the cause of freedom of conscience and purity of religion. Tyndal made the first translations of parts of the Bible into English from the original Hebrew and Greek. But although he went to the original tongues, he did not lay aside the Wycliffite version, but on the contrary he kept it in mind, if not before his eye, and seems to have endeavored to preserve its phraseology as far as was consistent with a faithful rendering of the original text and a necessary conformity to the general speech of his own day. To this endeavor we owe the continued life of that grand, strong, simple phraseology which English-speaking men recognize at once as "the language of the Bible," and which has for more than four hundred and fifty years exercised an elevating and purifying influence upon the English language and literature. Tyndal's translation is the most important literary and philological fact between the time of Chaucer and that known as the Elizabethan period. Tyndal was also a voluminous writer in commentary and controversy, and a stout and a successful disputant with Sir Thomas More. His English, like his thought, is notably vigorous, manly, and clear, and he with his followers—among whom John Frith, a Kentishman, was conspicuous—were the salt of English literature in the first part of the sixteenth century—a salt which has not yet lost its savor, which, let us hope, it never may lose to the taste of men of English blood. These men wrote in a simpler, homelier style, and in more nearly unmixed English words, than any writers after the beginning of the third quarter of their century. Archbishop Cranmer, and notably Bishop Latimer, were in their sermons and controversial writings apostles of simple English as well as of gospel truth. Latimer preached to the common people in their daily speech and with the most unstudied homeliness of diction and illustration. About this time there was an effort at English purism. Sir John Cheke, one of the few Greek scholars in England, began a translation of the New Testament, in which, as in his other writings, he was studious to represent Greek words by English equivalents, and went so far as to coin such words as *fore-shewers* for prophets, *hundreders* for centurions, and *again-birth* for regeneration. His friend Roger Ascham wrote his "Toxophilus" less to teach his countrymen how to draw the bow, which they had drawn pretty well at Hastings and at Agincourt, than to show them an example of a pure, idiomatic, and elegant English style, which he did most effectually. In this effort he was seconded heartily by Thomas Wilson in his "Arte of Rhetoricke" (A. D. 1553), and thirty years later by George Puttenham in his "Arte of English Poesy." All these critical writers condemn with little reserve what Wilson calls "inkhorne terms." But praiseworthy in certain respects as their efforts were, Anglo-Saxon and Norman-French were by this time too thoroughly welded together to be torn apart by criticism; and the addiction of the age to theological literature, which, written by "clerks," was filled with words and phrases transferred directly from the Latin, tended strongly to further Romanize the language.

Passing by the Northern poet, Gawin Douglas, we come upon the poets and prose-writers who were to usher in the brightest period of the world's literature since that outburst of Greek genius which took place in the age of Pericles.

John Skelton, Lord Surrey, and Sir Thomas Wyat were almost contemporary poets, but the first was in every respect singularly unlike the last two. Skelton was the more learned, and in his day had the greater reputation, Erasmus having styled him the light and ornament of English letters. But Erasmus doubtless had in mind only his Latin verses, which are esteemed by scholars as remarkably pure; for anything written in a "vulgar"—*i. e.* a living—tongue was even then regarded as much unworthy the considera-

tion of such a scholar as Erasmus. Skelton's English poetry is fantastic, extravagant, sometimes so incoherent as to be almost incomprehensible, and often so coarse as to be repulsive. But he introduced liveliness of movement and freedom of versification, much needed in English poetical literature, and with all his coarseness he was not without brightness of fancy and grace of expression. His "Philip Sparrow," a poem of nearly 1400 lines, has many passages distinguished in these respects. In his verse we find Romanic words still often, if not generally, accented in the Norman-French way—*e. g. licoûr, coloûr, succoûr.* He died A. D. 1529.

Sir Thomas Wyat, a traveller, a courtier, a satirist, and a writer of lyric poetry, was born A. D. 1537, and published his poems in 1557. He and his friend Lord Surrey (Henry Howard)—who translated part of the "Æneid," introduced blank verse into English poetry, and first wrote English sonnets—were the first true refiners of modern English style. They became the models of grace and elegance to their contemporaries and immediate successors. They died within a short time of each other, the former A. D. 1542, the latter on the block A. D. 1547.

We can only mention the names of Thomas Tusser (A. D. 1523–80), who wrote "A Hundred Points of Good Husbandrie," and whose verses have value only as bucolical antiquities; George Gascoigne, a dramatist, satirist, and critic of merit, who was one of the earliest of our writers of blank verse (A. D. 1536–77); and Thomas Sackville, earl of Dorset (A. D. 1527–1608), the author, with Thomas Norton, of the first regular English tragedy, "Gorboduc, or Ferrex and Porrex," which was also written in blank verse. But more than a passing notice must be taken of Sir Walter Raleigh, whose bright intellect, daring spirit, and chequered life make him one of the most conspicuous figures in English history and literature. Born (A. D. 1552) in the ranks of the gentry, but without advantages of fortune, he was a soldier, a courtier, a discoverer, a politician, a poet, and an historian; and in each and all of these various functions he won the applause and the envy of his contemporaries and the admiration of posterity. He was praised by Spenser, and his praise added to Spenser's glory. His poetry is remarkable for manly simplicity and freshness of feeling, mingled with sententiousness; his political writing for sagacity and knowledge of mankind; and his "History of the World" is full of wisdom, and closes with one of the grandest passages in English prose. He was beheaded in 1628, through the envy of the mean and crafty James I. and the envious persecution of a leading party of the court.

Somewhat like Raleigh in the circumstances of his life, although not at all so in the character of his mind, was Sir Philip Sidney. A younger scion of a noble family, he too was a soldier, a courtier, a scholar, and a poet. According to all accounts, he was the most accomplished, the most admirable, and the most lovable among English gentlemen of his day. Being elected king of Poland, he was prevented from accepting the honor by Queen Elizabeth, who was unwilling, as she said, "to lose the jewel of her times." He was a patron of literature as well as a man of letters. His claim to notice as an author in the history of English literature rests upon his "Arcadia," a collection of romantic and chivalric tales bound together with a slender thread of plan, somewhat longsome and wearisome, but full of graceful and animated passages; some poems, generally cold and conceitful, but in a few instances lofty in tone and lovely in imagery; but chiefly upon his "Apologie for Poetry," the earliest example of æsthetic criticism in our literature, and admirable for the beauty of its style and the soundness of its critical judgments, few of which have been set aside or superseded. Sidney first recognized the fact that the English language had been freed from the trammels of formal grammar. He was born A. D. 1554, and fell in 1586 on the field of Zutphen in Holland, giving up to a wounded soldier the water that was brought to slake his own dying thirst, saying, "Thy necessity is greater than mine."

Sidney has the credit, which he probably deserves, of having made possible the poetical career of one of England's greatest poets, Edmund Spenser. Spenser, born we know not exactly when, but about 1553, after having written "The Shepherd's Calendar," it is supposed at Penshurst, the seat of the Sidneys, where his friend Sir Philip took him to reside for some years, received a grant of 3000 acres of crown land in Ireland, whither he went and where he wrote the first three books of his "Fairie Queen," when, going to London to have them printed, Raleigh presented him to Queen Elizabeth, who, in consideration of his poem, gave him, in addition to his lands, a pension of £50, quite equal to $1500 now. There and then he wrote, among other poems, "Mother Hubbard's Tale." Returning to Ireland in 1592, he wrote two more books and two cantos of a third of his great poem; his series of eighty-eight sonnets; "Amoretti," celebrating his courtship of the lady whom he married; his "Epithalamion" on his marriage, "Colin Clout's Come Home Again," "Astrophel," and other poems. Driven from his home by some of the insurgents in Tyrone's rebellion, he returned to London, and died there in 1599. If not the greatest of the poets of the Elizabethan period (which may be regarded as including the half century from 1575 to 1625), Spenser was second to one only, and he was the greatest of all those who lived entirely in Elizabeth's reign. Among all English poets he has but two superiors—Shakspeare and Milton—although it is only in the elevation of his aim and in the fine and luminous flame of his fancy that he surpasses Chaucer. Spenser is the most purely poetical of all English poets. His great work, "The Fairie Queen," is poetry and nothing else. It is not dramatic, or theological, or satirical, or, strictly speaking, narrative; and although it did fashion "the twelve moral Virtues," it is not didactic after the weary fashion of most moral poems. It is allegorical, but its peculiar merit is not in the allegory; rather is the allegory somewhat of a hindrance to the reader who is not capable of setting the didactic purpose of the poem aside and enjoying for itself the golden wealth of its rich fancy. In its language it was somewhat old-fashioned for Spenser's own day. He used not only words that were not then familiar household words, but forms and inflections that had passed away; for instance, the old plural in *en*.

Among the Elizabethan writers a theologian like Richard Hooker (A. D. 1553–1600) must at least be mentioned. His sagacity and the logical clearness of his thought gained him the title of "the judicious," and his style places him high among the masters of English prose.

John Lyly's writings mark a change in the character of that prose. He introduced a fanciful and almost fantastical style of writing. He affected fine phrases, and wrote for courtiers and those who would have finer bread than is made of wheat. His language is much Romanized when compared with that of his immediate predecessors. The title, "The Euphuist" (one who speaks well), is derived from his principal work, "Euphues and his England," which had much influence, and even brought about a style of speech and writing called euphuism. But it would be very wrong to assume that this work is a mass of fanciful folly in affected language. The book is full of good sense and knowledge of the world. He also wrote six court comedies, which have little genuine dramatic interest, but which are very elegant and highly-finished productions of their kind. Born A. D. 1553, he died A. D. 1600.

Fulke Greville, Lord Brooke, "friend to Sir Philip Sidney," a poet, dramatist, and critical writer, whose style is cumbrous, but whose thought is far-reaching and weighty, can only be thus mentioned.

In the galaxy of poets that lighted up the Elizabethan sky even a merely superficial glance distinguishes William Warner, Samuel Daniel, Michael Drayton, Bishop Joseph Hall, Joshua Sylvester, and George Chapman, the first translator of the whole of Homer's poems into English, and whose version, often inexact and rude, has an occasional sinewy strength and pithiness and a felicity of phrase which his more polished and scholarly successors have not attained. Chapman was also a dramatist, but his dramatic work, although always indicative of poetic ability, was loose in structure and in style confused and headlong.

But we must hasten to the consideration of that remarkable school of writers, the Elizabethan dramatists proper. At this period the theatre was the chief intellectual entertainment of all classes and conditions of men, from the highest to the lowest. It filled the place now occupied by the novel and the newspaper. Young men of literary ability who found themselves in need of money in London turned to the stage as a means of supplying their necessities. The proprietors of the theatres kept poets in their pay, and ordered plays to be written sometimes by one, sometimes by two, and sometimes by half a dozen of their retainers. Conspicuous among these dramatic adventurers was Christopher or "Kit" Marlowe, a man of genius, but of genius wild, irregular, ill-trained. Both mind and man (if a man may be separated from his mind) lacked moral balance. The fierce extravagance and gilded bombast of his style can hardly be overrated; but from this turbid mass flash out gleams of brightest poetry. His characterization is often so strong as to be mere caricature, but it *is* characterization: his personages have individuality; and he first introduced the modern style of dramatic writing. To him also we owe the introduction of free and flowing blank verse upon the stage. His principal dramas are "Faustus," "Tamburlaine the Great," and "Edward II." Born about A. D. 1564, after a life of wretched irregularity he

was killed in a brawl, A. D. 1593. Colaborers with Marlowe were George Peele (about 1552–98) and Robert Greene (about 1560–92), men of much lighter weight and smaller calibre; the former an agreeable versifier and capable of tenderness; the latter essentially comic in the bent of his genius, giving us foretaste both of the high and the low comedy of after years. With these men there was a crowd of others who have left names, and even works, known to literary antiquarians, but long ago forgotten in literature and on the stage; but from among them sprang one in all supreme—the greatest poet, the greatest dramatist, the brightest intellect of recorded time.

William Shakspeare, the son of a Warwickshire yeoman and a lady of the minor gentry of that neighborhood (both of English or "Anglo-Saxon" blood), left Stratford (where he was born A. D. 1564) at about twenty-one years of age, and went to London as an adventurer. There he became a player and a playwright; obtained an interest in the company which played at the Blackfriars and Globe theatres; and by the plays which he wrote for this company—writing them as daily labor, just as a journalist now-a-days writes leading articles and criticisms—he made himself "the greatest name in all literature." To attempt here a criticism upon Shakspeare's genius would be futile. Briefly, it may be said that he owed nothing either to his predecessors or to his contemporaries, if we except the language in which he wrote and the form of his dramas, which were those of his time. He attempted nothing new; he simply was new himself—the most original, inexplicable, and hitherto absolutely unexplained fact in the history of literature. He seemed to know the secrets of nature and of man's heart, and to penetrate the depths of wisdom and of philosophy by intuition. He was a creator of his kind, for at a touch of his pen he spoke men and women into an existence individual and immortal. His style can hardly be described, it cannot be analyzed, and it has never been imitated. And there was no limit to the capacity of his genius. He sounded man's nature and the range of human thought from the top to the bottom of its compass. The grandest and the profoundest of all writers, he was at the same time not only the most delicate and the most fanciful, but the most comic. There is no tragedy, no philosophy, no pathos, no fancy, no humor like Shakspeare's tragedy, Shakspeare's philosophy, Shakspeare's pathos, Shakspeare's fancy, and Shakspeare's humor. We say all that we can say when we call them Shakspearian. To mention the titles of his principal dramas is quite needless. All the world knows that "Hamlet," "King Lear," "Othello," and "Macbeth" are his greatest tragedies, but it may well be said that his wisest play is one never played now and too little read—"Troilus and Cressida." He wrote at first in conjunction with other playwrights, after the manner of his time, but his facility in composition soon freed him almost altogether from the trammels of collaboration, and nearly all the great comedies, histories, and tragedies that bear his name are of his own unaided production. His Sonnets are inferior in thought and in expression only to his best plays. They alone would have won him immortality. His most inferior works are those upon which he labored most and rested the only literary fame he coveted—his poems "Venus and Adonis" and "Lucrece." He attained his purpose and retired to Stratford in the prime of life, a prosperous gentleman; and there he died A. D. 1616, entirely regardless of his poetic fame, having no predecessors or successors except in the order of time. None of his contemporaries were like him. There was an Elizabethan period of poetry and of the drama, but no Shakspearian school of either.

Chief among Shakspeare's contemporaries was his friend Benjamin Jonson, who for some time was regarded by the critical, but never by the public, as his superior. But gifted as Jonson was, the difference between them is so great as to be absolutely immeasurable. Jonson's best comic vein, as in "Every Man in his Humour," "The Alchemist," and "Bartholomew Fair," is simply a humorous—and yet not very humorous—picture of what passed before his eyes—persons and manners. His tragedy is an unsuccessful attempt at the imitation of classic models. In some of his tragedies founded on classic subjects—*e. g.* "Sejanus"—no inconsiderable part of the speeches are translations, more or less free, from Latin authors. He was overlaid with his learning. He was nevertheless a robust thinker, and at times a graceful one. Some of his minor poems, particularly his songs, have a peculiar charm which makes them the best known of all his works. He wrote one of our earliest English grammars, and in his "Timber" some of our earliest literary criticism.

Francis Beaumont (1586–1616) and John Fletcher (1576–1625), two gentlemen by birth, wrote together, although we have many plays by Fletcher alone. They were poets, wits, and dramatists, but not of a very high order, although of the high imaginative school. Comedy was their forte, and they first brought upon the English stage the comedy of intrigue. Their works are very voluminous, and suffer from a diffusion of powers by no means exhaustless. If they had written less they would have written better. Their most meritorious works are "The Maid's Tragedy," "The Elder Brother," "Philaster," and "The Faithful Shepherdess," the last of which was written by Fletcher alone, who had more fertility, more constructive power, and a livelier fancy than Beaumont.

Among the second-rate men of this period whose names only can be mentioned here were Philip Massinger (1584–1640), who had tragic powers, but who was destitute of fancy and humor; John Ford (1586–about 1639), whose forte was pathos; John Webster and John Marston, who dealt in the tragedy of horrors; Thomas Dekker, who had in a marked degree both pathos and humor, but whose wretched life gave him little opportunity to finish his work; John Middleton, a man of pleasing mediocrity; and Thomas Haywood, the most voluminous of them all, that being his chief distinction. James Shirley (1594–1666) closes the array of Elizabethan dramatists, and is the link between the times of Elizabeth and James and those of Charles and the Commonwealth.

Among the great intellects of the Elizabethan era only one man—and we might almost say hardly he—is more conspicuous than Francis Bacon. His universal misnomer is a notable recognition of his greatness. He became lord high chancellor and a peer, his title being Lord Verulam, but the man was far above his peerage, and he is called Lord Bacon. His distinction was in this, that he was the wisest man of modern times, almost the wisest of the sons of men. To no man since the revival of learning may the term "philosopher" be so well applied. As a scientific investigator he has had many superiors; his scheme of inductive philosophy may not be original; but if he had not written the "Novum Organon" he would yet have taken the stand which he has held for the two centuries, adown which from his sun-like mind has poured a blaze of intellectual light; for he had the grandeur and the poise and the far-reaching power which make a central luminary, and whatever he uttered bore the stamp of his supremacy. To English literature, strictly speaking, his contributions were not large, for the most of his writings were in Latin. His "Essays," by which he is chiefly known to general readers, were written in English, and they alone would have made his name immortal. Such a solid body of clear, compact wisdom was never uttered to the world from an uninspired source before his day or since. They show in every page the largeness, the breadth, and depth of his great intellect. In style they are models of concentration, giving results, not processes, and yet revealing the foundations of eternal truth upon which their judgments stand. Bacon was born in the reign of Elizabeth, A. D. 1561, and, living through that of James I., died in 1626. It is worthy of remark that there is no evidence in the writings of either that he and Shakspeare, the two brightest intellects of modern times, strictly contemporaries and living in the same place, knew of each other's existence; the reason of which strange fact is that one was a statesman and a philosopher, the other a player and a playwright.

In the reign of James, Robert Burton (1576–1640) produced the "Anatomy of Melancholy," a hash of curious learning made piquant by the original spice of splenetic humor and jocular sneers with which the quoted passages are seasoned to bring out their flavor. It is so filled with Latin that it is hardly an English book, but it is a typical specimen of a school or fashion of learned writing which prevailed about this time; and notwithstanding its pedantic air it has been, and ever will be, a source of delight and a quarry of suggestion to a large class of highly-cultivated readers, and greatly so to those who themselves are writers. The names of Donne (1573–1631), a metaphysical poet; of Sir Thomas Overbury (1581–1613), the author of "The Wife;" of Richard Sibbes (1577–1635), a Puritan divine; of John Hales (1584–1656), a theologian and the author of "Golden Remaines;" and of William Drummond of Hawthornden (1587–1649), a Scotch poet of merit and a historian of Scotland,—must be mentioned in an attempt to give a view of English literature at this period.

A notably important fact in regard to the Elizabethan era in literature is, that the English language, which was fully formed at the beginning of the sixteenth century, was used in that era with a freedom from formal restraint that since then has been unknown. The parts of speech changed places at the will of the writer. Not only were adverbs used as adjectives and adjectives as adverbs, but adverbs as nouns, and not only were nouns, but even pronouns, used as verbs. A like freedom reigned as to other parts of speech and in the construction of the sentence. Thus was born at a blow, in full strength and activity, the

genius of the English language, which is that the nature and quality of a word depend not upon its form, but upon its place in the sentence and its logical relation to other words. Thus the English of the Elizabethan period was more truly and absolutely English than that of any period before or since. This freedom prevailed most remarkably in the writings of the poets and the dramatists of the period, and chiefest of all the latter. But it pervaded all writing and all speech. That it was prevented from degenerating into chaotic license is probably due in a large measure to the preparation and diffusion of the revised or King James's translation of the Bible, which was published in 1611. In this translation, which was made with extremest care and the interchanged labor of forty-seven of the most competent scholars in England, the language of the previous versions was not only kept in view, but retained whenever it was consistent with the original, and sufficiently modern to be comprehensible without losing the dignity which pertains to antiquity, or taking on the strangeness which goes with novelty. The translators touched the sacred old structure with reverent hands, and while they renovated and strengthened it they did not whitewash the mellow tints of time with glaring newness. This book was at once published abroad throughout England, and since that time it has been printed and reprinted and scattered, and read daily by people of English race as no other book was ever read by any other people. Its influence upon English literature has been as great as—perhaps, alas! we should say even greater than—upon the morality of English life. It has been the treasure-house and the stronghold of the English language. It contains the best, the purest, the manliest, and the sweetest English that was ever written. Its narrative style is beyond that of all other writing in its own or in other tongues for simplicity, for clearness, and for strength. No exhortation is like its exhortation; no other counsel comes to us clothed in such impressive dignity of phrase. In it the rich and glowing diction of its Oriental original is preserved, and yet tempered with something of the cool directness, the honesty, and the homely freshness of the Anglo-Saxon nature. Its influence upon the English language has been the most pervading and the most wholesomely conservative that was ever exercised by a single force. Its authority has surpassed that of any possible Academy. It is a marvellous book; and whatever our faith or our lack of faith in the literal truth of all its declarations, it cannot be read with too much of admiration or of thankfulness.

After the death of Bacon and of James I. a few names of note attract our attention as we pass to the period of the Commonwealth: George Wither (A. D. 1588–1667), a poet chiefly sacred, nervous in style, and remarkable for his simple, clear English; Thomas Hobbes (A. D. 1588–1679), a writer upon social and moral subjects, a strong, clear, but not always logical thinker, and our first master of regularity and symmetry of style: he translated Homer into homely halting verse; Thomas Carew (died 1639), a tender and graceful writer of light amatory verse, which, based upon French models, has the merit of character; Robert Herrick (1591–1674), who, writing both sacred and amatory verse, is known chiefly by the latter, in which he clothes exquisite conceits in a rich, pulpy style; Isaac Walton (1593–1683), a meek and pious angler, whose love of nature and simple pedestrianism of life and style win him admirers generation after generation: he wrote "The Complete Angler" and the lives of Donne, Hooker, and other divines; George Herbert (1593–1632), whose collection of short poems called "The Temple" had an amazing popular favor, twenty thousand copies having been sold, according to his biographer Walton, in a few years. Herbert belongs to the metaphysical school of Donne. His thoughts are almost a continued succession of quaint conceits and are steeped in ecclesiasticism; but they are pervaded with the spirit of true piety and uttered in English notably simple and manly.

To the time of the Commonwealth and the Restoration belongs Edmund Waller, who was born A. D. 1605 to a large estate, and who devoted himself to politics and to literature. His verse unites grace and dignity, although he is sometimes tempted into extravagance. His lines "On a Girdle" express one of the most exquisite amatory fancies in our love-literature. He had a charming fancy, but little imagination. Contemporary with him were Thomas Randolph (1605–34), whose poems are tame, but in whose plays there linger echoes of the Elizabethan grandeur and freedom; Sir William Davenant, playwright and poet-laureate, but a poor creature: Sir John Suckling (1609–41), a dainty poet and an amorous; and the gallant Sir Richard Lovelace (about 1618–58), whose songs give the soul of chivalry and true love voice, but who loved honor more than love, whose cheery voice reaches us through his prison bars, and only dies with him in misery.

But all the poets of this period were eclipsed by the grand and luminous shadow of a man who was a schoolmaster and Latin secretary to the Commonwealth council of state—John Milton. Milton was of a Roman Catholic family of the minor gentry, but was born into a middle-class condition in life, his father having been disinherited for embracing the Protestant faith. His father, however, acquired money enough to retire into country life and to give his gifted son a university education (at Cambridge), to enable him to devote himself to study at home for five years after taking his master's degree, and then to travel on the Continent, particularly in Italy. He was summoned home by the beginning of the great civil war, in which he at once ranged himself with his pen—which being in the hands of a man "supremely great" was "mightier than the sword"—on the side of the Parliament. He went heart and soul into the struggle, and wrote many controversial works which need not here be noticed. Their value was chiefly for their time, and neither in them nor in any other of his prose works did his genius show, except fitfully, its peculiar power. Indeed, his prose, although strong in thought, is in style involved, cumbrous, and awkward. Of these the ablest are "Eikonoklastes," "A Defence of the People of England," "Tetrachordon," including "The Doctrine and Discipline of Divorce," "The Tenure of Kings and Magistrates," "A Tractate of Education," and "Areopagitica, a Plea for the Liberty of Unlicensed Printing." But it is as a poet that Milton lives in the world's memory, and of modern epic poets he is incomparably the greatest. His earlier and minor works have a serene and lofty grace of expression, united with a sustained power, that preludes the coming epos. But their merits, great as they are, are less imaginative than fanciful, although the fancy is of the very highest order. "L'Allegro" shows that he could even be playful. The phrase "the light fantastic toe" is quoted by thousands yearly who not only do not know whence it comes, but who would be surprised at learning that it was written by the grave Puritan author of "Paradise Lost." His sonnets have been much praised of later years, particularly since Wordsworth's saying that in his hand the sonnet "became a trumpet." And the opinion that most of them are unworthy of his genius, heavy in thought rather than weighty, cumbrous in style rather than stately, must perhaps be set down as peculiar to the present writer. Milton's genius did not adapt itself easily to small things. Like some huge birds he could not take a short flight gracefully. He needed space and time to soar on high and show the steady strength of his vast sweep of wing. These he found in the subject which he chose early for his great epic poem, upon the writing of which, after long previous incubation, he spent seven years. This poem has the singular advantage of the grandest theme, the theme most interesting to all Christendom, and the most suggestive of sublime thought, that could have been chosen. Had its author failed, even measurably, the subject would certainly have been taken up by some poet in after years; but occupying it absolutely and triumphantly as he did, it was ever afterward foreclosed against all comers. The style of the "Paradise Lost" in its finest and most characteristic passages has an almost indescribable grandeur and strength. Its lines are adorned with a wealth of illustration compelled from all literature and all history, sacred and profane; and its author marches along his royal road of verse like some great conqueror whose triumph is made splendid with the spoils of subject peoples. But these are the mere tokens and decorations of his own power. His thought and his purpose are always supreme. He is able to handle such subjects as omnipotence and archangelic rebellion, primeval purity and the ruin of a race, transcendent love, redemption, "fate, free-will, foreknowledge absolute," and to keep himself up to the lofty level of his stupendous theme. At least he very rarely falls below it; and on one occasion, at least, when he does so—the introduction of gunpowder and artillery into the fight between Satan and the Almighty—his error may be assigned to the unavoidable anthropomorphism of his machinery, and the then comparative novelty and terror of the engines of death which he used. There were neither fire-crackers nor revolving pistols in Milton's day. In the "Paradise Lost" and the "Paradise Regained" the poet worked out to the utmost bound of possibility mere hints in the sacred writings of the Hebrews and the Christians, and thus became the originator of many of the popular views of theology since his day. Milton is not, properly speaking, an English poet or an English prose-writer. His style and the very character of his thought are eminently un-English. His spirit is Hebraic, his form that of Latin and Greek models. His last work, and one of his greatest, "Samson Agonistes," is remarkable in this respect. In its form it is modelled upon Æschylus; its spirit is caught from Joshua, from Ezekiel, and from Isaiah. The hatred between the One-

God-loving race and the Gentile had had no such fierce and terrible utterance since the return from the second captivity. In one remarkable respect Milton is eminently un-English: he is entirely without humor, that peculiarly English, or at least Teutonic, quality of mind which manifests itself in some degree in almost every other eminent writer of that race. In all his controversial writing, savage as it is, there is no touch of humor. His only effort in this way—the suggestion that while the archangel and Adam talk in Eden, as Eve prepares their meal of fruits, there is "no fear lest dinner cool"—is one of the least happy among his few unhappy thoughts. Milton sold the copyright of the "Paradise Lost" for £5, and a further payment of £5 upon the sale of 1300, and £5 upon the sale of 1300 more. Milton received the first additional £5, the second edition having been published in 1674; and his widow parted with all her right in the copy for £8 upon the publication of the third edition in 1678; which must be regarded as a remarkable success for a poem of such a character at such a time. And yet Milton, celebrated as a controversial writer and a scholar almost from his youth, did not achieve fame as a poet during his lifetime. The "Paradise Lost" was not appreciated highly, not to say at its full worth, until after a series of criticisms by Addison in the "Spectator," and "Comus" and his other minor poems were first brought into general notice by Pope and Warburton. Milton, great as he was, does not stand in the front rank of poets—that is occupied by but three men, Homer, Dante, and Shakspeare—but first in the second rank without a doubt is the author of the "Paradise Lost." Milton, who had been blind for some years before he began to write out his great work by others' hands, died in London A. D. 1674. The creator of "Eve" married three wives, one of them "a saint," and was separated for a time from his first, not the saint. Of his three daughters, one was so unlettered that she could not write at all, and another could not spell her own name rightly.

Abraham Cowley (1618–67) was a contemporary of Milton of whom great things were thought during his lifetime and for many years afterwards. Milton himself, with that misappreciation of contemporary work so common even with great intellects, said that the three greatest English poets were Spenser, Shakspeare, and Cowley; an opinion extravagant to absurdity. Cowley produced no work of large design, but made translations and wrote "Pindaric Odes," "The Mistress," a collection of amatory verse, "Davideis," elegies, and the like. He belonged to the metaphysical school of Donne, of whom he was a weak imitator. His cold conceits and extravagant fancies are passing into deserved oblivion. Sir John Denham (1615–68) was his superior in every natural gift, and wrote in a much higher school, philosophical but cold. His "Cooper's Hill," his best work, will always command admiration for its nervous thought and fine imagery. It contains the fine apostrophe to the Thames:

> "Oh, could I flow like thee, and make thy stream
> My great example, as it is my theme—
> Though deep, yet clear; though gentle, yet not dull;
> Strong without rage; without o'erflowing, full;"

which is perhaps the most-to-be-admired example of that mosaic verse which was so much in vogue in the early part of the next century.

Of the prose-writers of the period of the Commonwealth, the most conspicuous and characteristic are Sir Thomas Browne (1605–82), Thomas Fuller (1608–61), Jeremy Taylor (1613–67), the earl of Clarendon (1609–74), and Richard Baxter (1615–91). Browne wrote "Religio Medici," "Pseudodoxia Epidemica, or a Treatise on Vulgar Errors," "Hydriotaphia, or a Treatise on Urn-Burial," and "The Garden of Cyrus." But notwithstanding the nature of these subjects and the fact that he was a physician, the interest of his writings does not consist in any contribution that he makes to morals, to science, or to the history of art. Their charm is only in the strange, fantastic thoughts which he weaves around his subjects in language which would have won him the applause of John Lyly the Euphuist. His vocabulary is so Romanized that it is hardly English. Jeremy Taylor, a Cavalier clergyman who became bishop of Down and Connor, has been called the Shakspeare and the Spenser of English prose. The latter comparison is the better. His style is like a rich tapestry full of glowing color and striking figures, that would be startling but for their beauty and their harmonious succession. Through the splendor of his fancy there runs a vein of sweet and tender yet glowing piety. His "Holy Living" and "Holy Dying" beget even in this faithless day a religious fervor in the reader. He has the honorable distinction of being the first earnest advocate of complete and absolute religious toleration, his argument for which is set forth in "Theologia Eclectica, a Discourse of the Liberty of Prophesying." Fuller exhibited in the highest, most typical form the witty divine—a character assumed by many of the clergymen of his period, who filled their sermons even upon the gravest themes with quips and quiddities and puns. He has the credit of being one of the wittiest, although not one of the most humorous, of English writers. The crackling of his jests is incessant, and although they are not always brilliant, they are rarely forced. His principal works are "The Holy and Profane State," "History of the Holy War," and "The Worthies of England." Clarendon was the first of our regular historians. His "History of the Rebellion and Civil Wars" is valuable chiefly because he was a witness of the facts which he relates with his judgment of the actors. His style is poor, often cumbrous, and often incorrect. Baxter was also a typical man. He was almost a perfect example of a clergyman who was a purely religious writer, rather than ecclesiastical or even theological. Fervor is his chief characteristic. His style is pure, and for its purpose it can hardly be, and never has been, surpassed. He wrote much, but is now chiefly known as the author of the "Saint's Everlasting Rest" and the "Call to the Unconverted."

But above all the prose-writers of this period, and high among those of any country or any time, rises one mighty figure—that of the Puritan tinker of Elstow, John Bunyan. "The Pilgrim's Progress," the book which has won its author a fame that like an English oak strengthens and broadens with the lapse of centuries, is an allegory purely religious in its original purpose; and of all allegories ever written it is the one which most effectually attained its end. But in its literary character, with which we have to do here, it is a work of fiction, a tale of human experience and of human passion, a story of trial, of struggle, of sorrow, and of triumph. Thus considered, it is matchless: in all literature there is nothing like it. Of its millions of readers, of all climes and all ages, comparatively few think while they read of its allegorical meaning. They are absorbed in the fortunes of Christian, of Faithful. To them Apollyon *is* the fiend and Giant Despair *is* the giant of which all the other fiends and giants of poetry and romance are the faint and feeble and theatrical imitations; and Greatheart is such a champion of distressed womanhood as might have shamed Cervantes into leaving his immortal satire unwritten. The youth who when he first reads it does not rush on "as if he would devour the way" must have a dull mind or a sluggish nature. The secret of all this is Bunyan's marvellous union of dramatic insight and dramatic power with a vivid and fiery imagination, beside which the imagination of all other prose-writers is pale and feebly imitative. Moreover, the style of the "Pilgrim's Progress"—not always correct, according to the laws of pedants and grammarians—shows a mastery of English in which its writer has no rival. It is an unconscious mastery, and it unites in absolute perfection strength and delicacy. Of no book except the Bible, and perhaps Shakspeare's plays, have so many copies been printed; and of no book without exception, we may be sure, have so many copies been read through and through again. It has been translated into nearly all the languages of the world; and of all peoples above the level of barbarism it has taken a mighty hold. Bunyan wrote another allegory of almost equal power, "The Holy War;" and his other works show his peculiar vigor of thought and of style. But the "Pilgrim" is his Moses' divining-rod. Bunyan was born in the humblest condition of life A. D. 1628, and after a life of poverty and persecution died A. D. 1688. A monument has been erected to him in his native village, and his statue stands in the new Houses of Parliament.

To the period of the Commonwealth we owe the appearance of the newspaper, which was to have such an influence upon society and upon literature. News-letters, as they were called, had been published earlier in the century, the oldest known being "News Out of Holland," published in 1619; but it was not until the exciting times of the Long Parliament that the genuine newspaper was demanded by the eagerness of the public for information as to what was taking place from day to day. Published at first once a week, newspapers at last came to be published every other day.

The political, religious, and social influences which were dominant during the Commonwealth were of an ascetic character, and tended strongly to the repression of the lighter forms of literature. For several years the theatres were closed, the drama was crushed, and lyric poetry languished. Upon the Restoration the repressed forces of society burst forth, and with the extravagance of reaction ran riot in high carnival. One of the earliest of the enduring fruits of the rank new growth was "Hudibras," a satirical poem by Samuel Butler (1612–80). The germ of this highly witty and humorous although coarse performance was in "Don Quixote." In Butler's poem the hero is

a Puritan knight in whom selfishness and hypocrisy take the place of the crazy chivalry and extravagant gallantry of the Knight of the Rueful Countenance. He too has a squire who greatly aids the dramatic movement of the composition. "Hudibras" was of course unfair to the Puritans, but it is choke full of knowledge of human nature, which is ventilated in witty expressions that succeed each other so rapidly and so sharply that it is like the letting off of a pack of fire-crackers. Not only Puritanism, but astrology, one of the weaknesses of the age, suffers dreadful exposure under the author's remorseless knife. Butler was the first English poet to make free use of double rhymes, upon the ridiculous effect of which many of his fine points depend. The couplet

> "Compound for sins they are inclined to
> By damning those they have no mind to,"

is a characteristic specimen of the gnomic portions of this immortal *jeu d'esprit*.

The dramatists of a period to which the court of Charles II. gave the tone were, as might be expected, not only free and gay, but licentious to the last degree. They revelled in the violation of external decency, and the nature of their plots was such that it would seem as if they were intended to illustrate the life of their royal master. All that they sought to present on the stage was amorous intrigue and wit; and it must be admitted that in both points they succeeded to admiration. Of the minor poets and wits of this period we shall make brief mention only of Charles Cotton (1630–87), who, besides his indecent verse, wrote the second part of the "Compleat Angler" and translated Montaigne into sound and nervous English; Sir George Etherege (about 1636–94), who wrote three plays, the best of which is "The Man of Mode," and who is the father of the modern comedy of intrigue; Sir Charles Sedley (1639–1701), a writer of exquisite wit and no less charming style; Wycherley (about 1640–1715); and the earl of Rochester (1647–80), the most indecent and perhaps the most gifted of them all, and who is the author of the best epigram (written on the bed-chamber door of Charles II.) in the language, for which he may be forgiven much:

> "Here lies our sovereign lord the king,
> Whose word no man relies on;
> He never says a foolish thing,
> And never does a wise one."

The chief poet of this period was John Dryden, the son of a Puritan gentleman, and who was born A. D. 1632. He began to write as early as 1649, but his most active period was from 1662 to the end of the century, his death occurring in 1700. Dryden began his poetical career in the school of Donne and Cowley, and in the extravagant absurdity of his conceits he out-Heroded Herod. Whoever wishes to learn what conceit is in poetry may best learn by studying it in the form of monstrous and loathsome caricature in Dryden's "Lines on the Death of Lord Hastings." But there was other stuff than this in the man, who merely began, as most young geniuses do, whether in literature, in music, or in painting, by imitating some one of their predecessors. Dryden, however, was nearly forty years old before he showed his power, which is that of an impetuous flow of versification, embodying cogent argument, stinging satire, or graphic portraiture. Of passion, of tenderness, and of pathos he showed none in his poetry, having, it would seem, none in his nature. He is fierce, but never warm, impetuous, but never earnest. He shows great strength, but not the greatest, which always carries with it a delicacy of touch to which weakness can never attain. His sentiments are never of the highest or the purest kind. He belongs to the race of time-servers and men-pleasers. But his satirical power is almost equal to Juvenal's, and his portraits of his contemporaries—as, for instance, in "Absalom and Achitophel," the best of his more important works—are grand historic caricatures, heroic in scale and in spirit. His best lyric composition, "Alexander's Feast," was once thought the finest thing of the kind in English literature, but time has been gradually, and surely and justly, diminishing its reputation. He wrote thirty plays, both comedies and tragedies. They have little poetic merit and no real dramatic power. They were, however, written as many of the best works in literature were written, merely for the money they would bring. But in the prefaces to some of these plays Dryden stepped upon the field of dramatic criticism, of which he showed himself a master. They are the earliest work of the kind in our language, and they remain among the very best. Dryden was not a great poet, but he seems like a great poet in arrested development. In another age, under different circumstances, he might have developed into a great poet if he had been more richly endowed with wider and warmer sympathies and deeper feeling. But lacking those he was suited to his time and he fulfilled his function. The perpetuity of his fame is due to the splendor of his style and the vigorous freedom of his versification. He was in these respects, and by his power of crowding an epigram into a couplet or touching off a portrait in a quatrain, the introducer of a new school in poetry, which prevailed during the early part of the century succeeding his death.

The latter part of the seventeenth century was adorned by several prose-writers of eminence other than those already mentioned: Ralph Cudworth (1617–88), Andrew Marvel (1620–78), Algernon Sydney (1621–84), Sir William Temple (1628–98), Isaac Barrow (1630–77), John Tillotson (1630–94), Robert South (1633–1726), and Gilbert Burnet (1643–1715); as to whom, however, we can spare room enough only for their names. But one man of this period, John Locke, demands more particular attention, as being an original thinker and one of the most eminent of England's philosophical writers. Locke is indeed the father of political and social ideas which since his time have shaped the political and the social development of the English race in Great Britain and America. In his "Considerations of the Consequences of Lowering the Interest and Raising the Value of Money" he first taught the political and commercial necessity of absolute good faith on the part of government as the creator of the legal representative of value and the medium of exchange of commodities, and that the issue of a depreciated currency was a breach of good faith. In his "Letter concerning Toleration" he not only nobly sustains the arguments of Milton and Jeremy Taylor on the same subject, but he broaches the theory now established and acted upon, that the function of government is to make secure the personal liberty and the civil interests of the individual, and that when it attempts to do more it oversteps its proper limits. His "Treatises on Civil Government" develop and enforce this important political theory, resting it chiefly on an implied contract between the governing power and the governed. His "Thoughts concerning Education" have controlled, and wisely controlled, the action of the English peoples almost until the present time, although the cold austerity of his views has been modified by a warmer infusion of parental feeling. But it is his "Essay concerning Human Understanding" which has given him his most enduring fame and power, in that he was the first to popularize the study of mental philosophy, and to turn the mind's eye of the whole world inward upon itself. To John Locke more than to any other writer is owing the introspective character of the literature, even the imaginative and fictitious literature, of the present age. Of Locke it was justly and admirably said by Mackintosh that "his writings have diffused throughout the world the love of civil liberty, the spirit of toleration in religious differences, the disposition to reject whatever is obscure, fantastical, or hypothetical in speculation, to reduce verbal disputes to their proper value, to abandon problems which admit of no solution, to distrust whatever cannot be clearly expressed, to render theory the simple explanation of facts, and to prefer those studies which most directly contribute to human happiness." His style has the fault of being in spirit unimaginative and in form too diffuse and vague. He was born in 1632 and died in 1704. He is to be read not for his manner, but his matter.

Contemporary with Locke were two distinguished men of science, one of them of the first eminence—Robert Hooke and Sir Isaac Newton. Hooke (1635–1703) was an investigator and an inventor, but chiefly a critic and a disputant, presuming, ill-tempered, and insolent. He did not hesitate to attack Newton's theory of light and colors. Newton (1642–1727) is admitted to have been the greatest master of exact science that ever lived. His discovery of the law according to which the force of gravitation acts, and of the refraction and composite nature of the ray of light, are the most important in their kind of modern times. His genius, although sublime and far-reaching, was eminently practical; and to him England was indebted for the regulation of the dire confusion of her coinage. His works hardly come within the range of pure literature, but the splendor of his genius and the grandeur of his fame forbid them to be passed by without notice.

Locke and Newton were the great literary and philosophical ornaments of the reign of William and Mary, which was sadly in need of all the glory that could be shed upon it by their genius; for the Revolution of 1688 crushed literature far more effectually than that did which brought in the Commonwealth; one reason of which doubtless is that there was a much feebler thing to crush. For twenty years the annals of literature are bare of interest except that which attaches to Locke and to an early performance of Matthew Prior's "The Country Mouse and City Mouse." But Prior's career (1664–1721) stretched well into the eighteenth century, in the first quarter of which appeared that galaxy of admirable writers known as the wits of Queen Anne, among

whom Prior must be reckoned. The others were Swift, Pope, Steele, Addison, Gay, Garth, and Arbuthnot; of whom the last three, with Prior, may be passed without further notice.

Jonathan Swift, Irish by birth (1667), but the most English of men by blood and nature, first appeared in literature by the publication in 1704 of his renowned "Tale of a Tub" and "Battle of the Books," the former a religious satire, the latter a literary one, both highly flavored with a coarse kind of comedy. The success of these works was very great, and their reputation has continued even to the present day. But it is safe to say that only their reputation has survived; and that there are few even of the most cultivated readers now-a-days who can read these comic allegories (for such they are) with much enjoyment of their wit, or even with a very keen appreciation of their satire. But their writer has few equals as a wit or as a satirist in any literature. When he stepped upon the broad field of human nature he produced that which will be the source of delight and instruction until human nature has become other than that which he found it. It is as the author of "Travels by Lemuel Gulliver" that he commands the widest circle of readers. This production had a political purpose, like most of its author's works, and contains allusions to and caricatures of some of the statesmen, churchmen, and other public men of that day; but the genius of its author impelled him to deal with mankind even more than with party, and his satire is upon the human race. This is indeed the weakness as well as the strength of Swift's writing—his contempt for his fellow-men. His own personal tastes, no less than his personal feelings, put in a strong appearance in all his writings; and nothing does he show with so little reserve as his aversion from his kind. The disgust which he makes the king of the horses in his "Houyhnhnms" feel for the Yahoos is plainly but an utterance of his own sentiments. Christ tells us to love our enemies: this Christian minister seems to have hated his friends. But notwithstanding this unpardonable sin against the holy spirit of humanity, notwithstanding an indecency which does not consist in a public exposure of those ardent passions which the least reserved of men conceal, but in a revelling in physical filth, Swift's insight into men's motives is so keen, his satire is so splendid, as well as so savage, his wit and humor are so fine and so continuous, and his style so simple and so nervous, that great pleasure and good counsel can be extracted from almost all that he wrote. He has been compared to both Rabelais and Cervantes. He was far below either in spirit and purpose, but more like the former than the latter in his style. He wrote poetry, or rather verse, which had all the characteristics of his prose, and no others, being entirely without imagination, fancy, or beauty of form. His best known works, in addition to those already mentioned, are the "Drapier Letters," "Polite Conversation," "Directions for Servants," and "Modest Proposal for Preventing the Children of Poor People in Ireland from being a Burden to their Parents, and for making them Beneficial to the Publick"—to wit, by eating them. He died in a state of wretched imbecility A. D. 1745; and it is not improbable that his intense egoism made him somewhat mad, with a selfish method in his madness, during no small part of his life.

Alexander Pope, born A. D. 1688 of Roman Catholic parentage, began to write verses in his childhood, and before he was thirty years old had amassed a moderate fortune by his pen, and had taken a position which makes his name the most illustrious in the literary roll of the eighteenth century. Pope's first work of conspicuous merit was the "Essay on Criticism," written when he was but twenty-one or twenty-two years old. Containing no new or striking views of literature, it is yet admirable for the soundness of its judgments and the epigrammatic elegance of its style. His "Rape of the Lock," a mock-heroic poem—in fact, a burlesque social epic—is the most charming and exquisitely finished composition of its kind ever written. Pope was, like Dryden, whom he began by imitating, a satirist, and, like Swift, an egoist. But, unlike either of them, he had tact and delicacy, and was an accomplished man of the world. Where one used a broadsword and the other a bludgeon, he used a rapier. His mind had also a strong philosophical turn, and this he showed in his "Essay on Man," which is the finest didactic poem in any language, unmatched for closeness of thought, felicity of illustration, and delicacy of finish. He never wrote with passion or with strong imagination, but in his "Epistles of Eloisa to Abelard" and "Sappho to Phaon" he did attain a warmth of feeling which is almost like the fervor of real love; and in writing of his own feeble, crippled, weary physical life ("Epistle to Arbuthnot") he utters his woes with a simple pathos which is touching and dignified. With the assistance of some minor versifiers of the day he translated Homer, making a brilliant and very readable version, which has the one great defect of misrepresenting the original both in form and in spirit. He edited Shakspeare, but his real editorial work is of little worth, and the only valuable part of the edition is in the preface, which is full of excellent criticism written generally in admirable English. Pope was not a great poet; he was rather a colossal epigrammatist and the most skilful of versifiers. He wrote almost always in the ten-syllable heroic couplet, which he brought to the highest perfection of which it seems to be capable. He died in affluence A. D. 1744, having established a school of poetry, and leaving hosts of imitators, who filled the first half of the eighteenth century with evidences of how easy it was to imitate his form, but how hard to attain his finish or to approach his style of thought. His last important work was the "Dunciad," a savage satire not easily understood now by those who are not familiar with the literary squabbles of his day. Satire has its place in literature, and

> "is of use
> To teach good manners and to curb abuse,"

but personal satire is not always admirable, or even justifiable; and it is sad to reflect how much fine ability has been prostituted to the mean purpose of giving personal pain.

Two of the eminent men of this period are not only nobly free from the reproach of injurious motives and of egoism, but remarkable for the humanizing and elevating purpose of their writings: they are Richard Steele and Joseph Addison. To the former we owe the introduction into our literature of the brief periodical essay, which since his time has held such an important place in our literature; and we owe to him also the bringing to light the remarkable powers of the latter, the master of this kind of writing. Steele began the publication of the "Tatler" in 1709. It appeared three times a week, and only a few numbers had been published when he induced Addison to become one of its regular contributors, the others being Swift and Hughes. Addison wrote about fifty papers. Afterward, in the "Spectator," Addison assumed a more important position, and wrote most of the papers which gave that publication its unrivalled reputation. The purpose of Steele and Addison was the elevation of English society in intellectual and moral tone, and in manners. This they accomplished by a series of papers which have never been surpassed in the easy charm of their style, and in which wit and satire were directed, not against individuals, but against grossness, meanness, and frivolity, and which did more than any one other single agency to diffuse a taste for literature, for art, and for all the refinements of social life among English-speaking peoples. Addison's style, although not nearly so correct as it was once supposed to be, deserves for many qualities all the admiration that it has received. For its constant grace and its general clearness, for lambent humor, for good-nature, wit which like Ariel's music gives delight and hurts not, for a certain tone of social elegance, and for a purity far remote from squeamishness, it has no superior, hardly an equal. Addison's literary criticisms in the "Spectator" first raised that department of English literature into a recognized art. To him, as it has been said above, English literature owes the establishment of Milton's fame. In this respect, as in matters of society, he was a benefactor to the English people. Nor was Steele much behind him. Less profound and subtle than his great colleague, less exquisite in his humor, he had a larger heart and a richer nature, and there is a warm cordiality in his writing, the lack of which is Addison's chief defect. But throughout the papers published by this admirable pair there is a dignified familiarity which has a peculiar charm, and the characters to which they introduce us become our valued acquaintances, and almost our friends. Sir Roger de Coverley is not only an historical type, but a man that we know and love and admire. Steele and Addison both wrote plays, the former a few comedies of some merit, the latter a cold, didactic, classical tragedy, "Cato," which enjoyed for a time a considerable reputation. But it is as the essayists of the "Tatler," the "Spectator," and the "Guardian" that their names live in our grateful memories. Addison died in 1719, Steele in 1729. Like Pope, they established a school, and their century was filled with their imitators, whose writings, often not without merit, demand no particular attention. But we must mention Lady Mary Wortley Montague (1690–1762), whose letters are models of the familiar epistolary style.

We must turn back a few years for a brief consideration of three dramatic writers who gave some brilliancy to our stage in the reigns of William III. and of Anne—William Congreve (1670–1729), John Vanbrugh (1606–97), and George Farquhar (1678–1707). Of these, Congreve was the man of highest aims. He was poetical, if not a poet, and wrote sententious verse in a dramatic form. His

tragedy, "The Mourning Bride," contains some passages which are still remembered; in his comedies his wit keeps up a continual flash as of heat-lightning. But he created no character and had no real dramatic force. Vanbrugh had what Congreve lacked, and lacked what Congreve had, except wit. His plots are ingeniously constructed, and his characters are strongly if not truthfully drawn. Farquhar's comedies are chiefly remarkable for a flow of animal spirits. But no one of these men added much to the real glory of the English drama.

In the year when Addison died there appeared a work of fiction which has been more widely read than any other in English fiction, except perhaps "The Pilgrim's Progress." It was "The Life and Strange Surpassing Adventures of Robinson Crusoe, Mariner." Its author, Daniel Defoe, was then fifty-eight years old, having passed his life until that very mature period chiefly in writing an almost incredible number of political pamphlets in favor of liberal or Whig principles. "Robinson Crusoe" immediately commanded the attention of all sorts and conditions of men. It was read with avidity, and not only with avidity, but with credulity. It was not looked upon as a novel, a fiction from beginning to end: it was accepted as a plain, unvarnished narrative of fact. And in the quality which caused it to produce this impression is its great and its only merit. Defoe has, in a greater degree than any other writer, the art of giving to fiction the air of reality. So impressive is the real-seeming of his stories that when, as we are reading, we pause for a moment and reflect that they are not true, we are startled; for then it seems as if our own lives and all that goes on around us might also be fiction. This effect is a consequence of a certain strength of imagination; but it is also due in a great measure to the continuous relation of trifling, matter-of-course, and utterly insignificant events, which, being told naturally, seem as if they were part of a life passing minute by minute before us—an inferior kind of imagination and of constructiveness, reducing that which is produced by it to the lowest level of the real school of art. Defoe was a manly and an incorruptible political writer; but as a literary artist he had the grand and fatal defects of a want of passion, of sentiment, and of tenderness, and also of any remarkable insight into character and power of portraying it. His "History of the Plague" is as real-seeming as "Robinson Crusoe," and is almost as purely fiction. His other works are now little read, and his satirical poem, "The True-born Englishman," is known chiefly by name. Born in 1663, he died in 1731.

After Swift and Pope and Addison and Steele had ceased to write there was a long dearth of originality in English literature. But contemporary with them, or immediately following them, we have to notice among the poets Matthew Prior (1664–1742); Isaac Watts (1674–1748); Edward Young (1681–1765); Thomas Warton (1687–1745); John Gay (1688–1732); William Collins (1720–56), whose "Odes" are among the best we have; and, far superior to all the others, yet still a poet of the third or fourth class, James Thomson (1700–48), author of "The Seasons" and "The Castle of Indolence." Among the prose-writers of the period the following demand honorable mention: Richard Bentley (1662–1741), eminent as a classical scholar and critic; Lord Shaftesbury (1671–1713), whose "Characteristics" are elegant, independent, thoughtful, but not profound; George Berkeley (1684–1753), who became bishop of Cloyne, and who broached an ideal system of philosophy, the cardinal principle of which was that perception is all that we know of reality; and Lord Chesterfield (1694–1773), the apostle of etiquette and good breeding.

In the middle of the eighteenth century the English people were startled by the sudden appearance in fiction of *nature*, an element which had been previously unknown therein. Defoe's power had been that of reality, which is akin to nature, but is not nature. The new style was introduced by Samuel Richardson, a man born in humble life, bred to a mechanical trade, and finally a bookseller. He at the age of fifty-two produced "Pamela," which was followed by "Clarissa Harlowe" and "Sir Charles Grandison." The success of these books, particularly of the first and second, was prodigious. But as we look back at them, and wade through the endless succession of letters from and to their high-strung, sentimental heroines, we wonder at the avidity with which such masses of moral "spooning" were devoured, and can attribute such appetites only to a long course of starvation. Or, as Scott, in his explanation of this phenomenon, says, "Had we been acquainted with the huge folios of inanity over which our ancestors yawned, we should have understood the delight they must have experienced from this unexpected return to truth and nature." Richardson was minute, like Defoe, and his personages being flesh-and-blood creatures of the period, and his sentiment genuine of its kind, although inordinate in quantity, he also awakened the keen interest which always watches over the vicissitudes of those whose experience is what we feel that ours might have been. But his books are a weariness to the flesh. It may be possible for some people now to read all of "Pamela," but who for two generations has been able to struggle through "Clarissa Harlowe" and "Sir Charles Grandison"?—the hero of which is like a Washington in plain clothes turned beau, and eternally bowing over the hand of some pretty piece of female propriety, who worships him as if, instead of being a man, he were a fetish. But Richardson was the occasion of the appearance of a real master of human nature. Henry Fielding (1707–54), a gentleman by birth and a man of liberal education, was tempted to write a burlesque of "Pamela:" and, as in the case of some other performances of like motive, the burlesque proved more true to nature than the original. Fielding's novel was "Joseph Andrews;" and as Pamela's chief object of life was to preserve through six or seven volumes the point of female honor, so Joseph, her supposed brother, devotes himself to the assertion and preservation of his continence against the wiles of the opposite sex. The vigor and spirit of Fielding's style and his creative power have never been surpassed. He showed that highest ability in fiction, the power of creating personages which are at once individuals and types. His Parson Adams, Lady Booby, Squire Western, Tom Jones, and Amelia have a vitality and a truth far above that which is producible by the most elaborate work in the realistic school. They come from a knowledge of the real, from which the truth of highest art eliminates the non-essential. They are created from within, not built up from without. Fielding's humor is rich, free, and pervades his comic scenes like the natural atmosphere. That he was sometimes coarse, according to modern standards of taste, is the fault of his time. Tobias Smollett (1721–71), who soon appeared upon the field, was a much coarser artist. His object seems merely to tickle his reader into laughter by a succession of scenes which seem like farce put into narrative form. But he has fine touches of satirical humor, and his "Peregrine Pickle" and "Roderick Random" and "Humphrey Clinker" will always give pleasure to readers of robust tastes and strong stomachs. In the latter part of his life he wrote a continuation of the history of England from the point to which it was brought down by Hume, who next engages our attention.

David Hume (1711–76) was a Scotchman, who first appeared in the field of philosophy, in which he showed himself an original and daring thinker. His philosophical works are a "Treatise on Human Nature" (republished as "Philosophical Essays concerning the Human Understanding"), "An Inquiry concerning the Principles of Morals," and "The Natural History of Religion." In the treatment of these subjects he disregarded authority and accepted belief, making fact and reason his only guides. He was by nature a doubter and an inquirer. These works placed him in the front rank of modern moral and metaphysical writers, and produced an effect which seems destined to be permanent. His views as to the possibility and the necessity of miracles arrayed against him all the theologians of his day; but a large number of the ablest and most sincere theologians of the present time accept his views, as being sound in the main and not at war with the interests of true religion. Having taken this position, he turned his attention to history, and wrote in three instalments what is known as his "History of England," bringing his work down to the Revolution of 1688. This work is not of high authority as to matters of fact, and it is strongly tinctured with the writer's personal prejudices. But its happy arrangement, the clearness and vivacity of its style, its charity and toleration of spirit, notwithstanding the obvious prejudices before referred to, make it one of the most interesting of modern histories, as it was the first of the modern school of historical writing. Hume's style is too strongly marked with Northern peculiarities to be regarded as a good example of standard English.

Contemporary with Hume, but younger than he, was Edward Gibbon (1737–94), who produced between 1776 and 1788 his "History of the Decline and Fall of the Roman Empire," a work upon which he was engaged for twenty years. The magnificent plan of this history, the vast extent of time which it covers, its colossal erudition—it being the fruit of original investigation of facts hidden for the most part in the dimmest recesses of the Dark Ages—and its imposing style, make it the greatest work of its kind known to literature. Its style, however, is too conscious, too pretentious, too much infested with Romanic words and Gallic forms of thought, to be regarded as really English. It is Gibbonese.

Forming one of a group of three contemporary historical writers of eminence was William Robertson (1721–93), who wrote the history of Scotland, of Charles V., and of Amer-

ica—works of sound and unpretending merit, written in an agreeable style, somewhat too strongly marked with Scotticisms.

The middle of the eighteenth century was adorned by the brief but highly-finished poems of Thomas Gray (1716–71), whose function in poetry seemed to be to show how high a point could be reached by a man who had a poetic nature, strong poetic feeling, and an exquisite ear for rhythm, but who was without genuine poetic inspiration. Gray's "Elegy in a Country Churchyard" has probably been more widely read than any other poem in the language, and it has certainly furnished more phrases to our collection of household words than any other that ever was written; almost the whole of it has become a part of familiar speech. It is a beautiful union of tender thoughtfulness and graceful expression. Contemporary with Gray was William Shenstone (1714–63), a poet of considerable merit, whose best-remembered work is "The Schoolmistress," an admirable imitation of Spenser's style, but more admirable as a poetical picture of a type and of a time.

To this period, too, we owe the works of Laurence Sterne (1713–68), one of the greatest humorists in English or in any other literature. His is the only humor that could be named with that of Shakspeare or of Cervantes. His satire has the charm of a delicacy so exquisite that it seems like pungent aroma filling the atmosphere of his thought. His style has a corresponding daintiness, although it is sometimes disfigured with affectation. Admiration of "The Life and Opinions of Tristram Shandy" and of "A Sentimental Journey through France and Italy" has grown with the passage of each year since their first appearance.

Throwing the shadow of its sad humanity all athwart the latter half of the eighteenth century stands the burly bulk of Samuel Johnson, who was born in Litchfield A. D. 1709, and died in London A. D. 1784. Johnson was one of the most miscellaneous, and really one of the most desultory, of writers. He was a poet, a dramatist, an essayist, a biographer, and a lexicographer. In fact, like many other literary men of equal and of less note, he wrote for bread that which he was called upon to write; but he impressed upon all that he did write the stamp of his own strong individuality. His purely literary fame was acquired chiefly as a moral and a critical writer. Not always just, not always right (who is?), he is distinguished by a love of truth and of purity, by sturdy independence and colossal common sense. Of original thought he produced little, but he added to axioms the charm of novelty by the earnestness and the weight with which he gave them utterance. His style, too ponderous and too formal, has nevertheless the great merit of clearness and of strength; and it would be well if many of the shambling, slipshod writers of the present day would take a hint from his advice in regard to Addison, and give their days and nights to the study of "the Johnsonian period." His "Rambler" essays, which he wrote twice a week for two years, exhibit in their most characteristic form his merits and his defects as a writer. If heavy sometimes in style, they are always laden with the weight of humanity. Johnson's "Dictionary," having been compiled before the establishment of the modern school of comparative philology, has comparatively little etymological value, but it was the first English dictionary made upon the proper principle of an investigation of the history of words as exhibited in English literature; and it has been the model and the quarry of almost all subsequent works of its kind. Johnson is, however, best known through the minute report of his daily life and his intercourse with his literary friends furnished in his memoirs by James Boswell. He was a sort of king in the literary circles of his time, and exercised a personal influence the effects of which have not yet quite passed away. He was often overbearing, and sometimes even brutal; but nevertheless he stands, rugged, sad, tender, generous, true, a solemn figure to be admired, and even loved.

Among his eminent contemporaries two must be passed by with mention inadequate to their merits or their fame—Adam Smith (1723–90), who has the honor of being the founder of the science of political economy; and Sir Philip Francis (1740–1818), who under the signature of "Junius" was a terror to the statesmen of his time, and even of his party; and who remains the great English master of invective. The style of the letters of Junius is still worthy of all the admiration of which they were ever made the subject; and that of the best political leading articles in the journalism of subsequent times owes much to those celebrated letters, which may be said to have founded the modern school of anonymous and irresponsible journalism.

It is remarkable that of the great masters of modern English, four of the greatest were by birth and early education Irishmen—Swift, Sterne, Goldsmith, and Burke—and of these the foremost is the last. Edmund Burke (born 1736) is beyond all doubt the greatest master of English prose. Goldsmith is his equal in purity, simplicity, and grace; but in Burke there is a fulness of thought, a wealth of words, a sustained power of utterance, a grand sweep of the period, with a subtle yet most naturally inwrought richness of illustration, to say nothing of mere accuracy of expression and clearness of construction, which place him far beyond all other writers. Burke's mastery of language is like Beethoven's mastery of melody and harmony. His department of literature is that of philosophical statesmanship, in which he stands side by side with Cicero, if not a little before the great Roman. The saying that he to party "gave up what was meant for mankind" is one of those glittering fallacies of thought which poets have unfortunately the power of perpetuating. On the contrary, his fault as a party-man was that he thought too much of mankind and had too much poetic feeling—thought perhaps not always logically, and sometimes with too much sentiment of the highest kind, but rarely in unwisdom. Indeed, he is the wisest of all modern politicians. His "Reflections on the Revolution in France," "Letter on a Regicide Peace," and "Letter to a Noble Lord" are his principal works. Of his purely literary essays, that on "The Sublime and Beautiful" was at first widely known and read. But among the earliest fruits of his laborious life it is that of the least permanent value. His strength grew with his years, and his most powerful as well as his most brilliant efforts were made after he had passed his meridian, and even just before his death, which took place in 1797.

Of Goldsmith (1728–74) Dr. Johnson well wrote, "Nullum non tetigit quod non ornavit," and he touched many things, but he lives in literature as the author of four works of very various form: a novel, "The Vicar of Wakefield," a comedy, "She Stoops to Conquer," a poem, "The Deserted Village," and a satirical criticism of society, "The Citizen of the World." He wrote other poems, many essays, and much criticism, all charming in style and full of humor and a gentle wisdom, but the works named above are his masterpieces. The "Vicar of Wakefield," faulty in construction, is matchless and immortal as a gentle revelation of the weakness of human nature, and is the first of our novels of domestic life; and "She Stoops to Conquer" is, whether for its construction or its humor, the best comedy of the same range in English dramatic literature.

The eighteenth century was rounded with the life of a poet, William Cowper (1731–1800), who to minds of a religious tone and unspeculative cast speaks in accents which cherish and comfort them and sustain their faith. He is pre-eminently the poet of Christian morality, of true piety, and of all the softer and sweeter social graces. Incapable of bitterness, he was not incapable of gentle and dignified satire; and although his style has too much of the formality and conscious precision of his time, he has many passages marked with great sweetness and freshness of feeling. His longest and most ambitious original works are "The Table Talk" and "The Task," but incomparably his best are his "Lines on my Mother's Picture" and "John Gilpin," an outburst of pure fun and humor strangely and delightfully incongruous with his usual style. He translated Homer very ambitiously, but without corresponding success.

Robert Burns (1759–96), who died only four years before Cowper, was the greatest writer of English poetry born north of the Tweed. He is regarded as a "Scotch" poet, but even his "Scotch" poems are in a mere dialect of the English language, as has been remarked above; and some of his more serious poems, and not a few of his songs, are in as pure standard English as any compositions of his contemporary, Cowper himself. As a lyric poet, Burns, when we consider both the number of his poems and their merit, must be placed at the head of his class. No songs so full of the direct utterance of passion, of tenderness, and of love-lit fancy exist in the English language—hardly in any other; and his idyls spring from the soil like grass, and with the purple bloom and the sweetness of heather. Entirely uninstructed, he was fashioned by Nature from his cradle to be her singer. The very trials of his shifting life, the very failings of his unstable character, were to him sources of the purest poetic utterance. He indeed did learn in suffering what he taught in song. Having wrecked his life upon his passions, and wreaked his woes upon expression, he died in misery, and left a name around which burns a glow of tender glory. Two of his countrymen deserve mention among the poets of their land—James Hogg (1772–1835) and Allan Cunningham (1785–1842).

In the eighteenth century the English race began to manifest its power in a new quarter of the world. The men who had left the old England, and had crossed the

Atlantic to found a new England free from some of the civil and religious restraints which galled them in the land of their birth, were, very many of them, not only energetic and enterprising, but intelligent, and of more than moderate intellectual and social culture. In New England education was one of their earliest cares. Colonial literature has, however, nothing worthy of notice in a sketch like the present (for the Mathers, Increase, the father, and Cotton, the son, produced nothing that has any intrinsic literary value) until we reach Jonathan Edwards (1703–58), a theological and metaphysical writer whose power was at once recognized in the mother-country, and whose "Enquiry into the Freedom of the Will" is still the stronghold of the necessitarian theologists. He merited the judgment pronounced by his biographer Mark Hopkins, that he was a man of considerable learning, extensive reading, sound judgment, and great argumentative acuteness. The next author of eminence among his countrymen was Benjamin Franklin (1706-90), the great apostle of common sense. Franklin was a philosopher, but in his company Philosophy wore her homeliest garb and addressed herself by the simplest means to the most practically useful ends. He was above all things "utilitarian," of which school in social science he was one of the founders. He is hardly better known for his discoveries in electricity and the great diplomatic services he rendered the colonies at European courts than for the prudential maxims of his "Poor Richard's Almanac." His style is very plain, clear, and convincing. Among Franklin's younger contemporaries were the men who roused the colonists to resistance to the tyrannical government of George III., and finally brought about the severance from the mother-country—John Adams (1735–1826), Thomas Jefferson (1743–1826), Patrick Henry (1736-99), Thomas Paine (1737–1809), Jonathan Trumbull (1750–1831), Philip Freneau (1752–1832), and Alexander Hamilton (1757–1804). Of these, Adams was sound in judgment, logical in reasoning, a lawyer, and a man having respect for authority and demanding respect for it; Jefferson a calm but earnest and persistent advocate of equality before the law in all things, whose authorship of the Declaration of Independence not only secures him immortality, but gives him some claim to having helped to light the fires of the French Revolution; Patrick Henry an orator of masculine tone and fervid phrase, equally daring and dexterous; Thomas Paine an intellectual iconoclast and a rebel against all authority, whose "Common Sense" and "Rights of Man" have done more to spread skepticism, if not to quicken it, than any other books ever written; Philip Freneau a poet of genuine patriotic feeling and lyrical skill; Hamilton a statesman of true formative power, who was endowed with the ability of uttering his schemes and putting his arguments in a style of remarkable elegance and force. He was the principal author of "The Federalist," a series of papers which did much to bring about the formation of the American Union. But the place of all these men in literature is not a notable one, and is very inconsiderable compared to that which they filled in the great political movement of their time. They had very little influence on the literary tone of their own country, and are hardly discernible in the great stream of English literature which now flows yearly fuller and stronger with the inpouring of its American tributary. But it was not until well on in the first quarter of the nineteenth century that Anglo-American writers showed native, independent power.

The period succeeding the American war of Independence and the French Revolution was one of great activity in English literature, all departments of which were filled by a throng of new writers who sprang up with the spontaneousness of mushrooms, but not with their shortness of life. And now, as there are no longer any material or significant changes in language to be noticed, as authors crowd upon us—authorship having become so common that we all write, learned and unlearned—and as we have reached a period within the memory of living men, our remarks, even upon writers of eminence, must be more brief than they have been heretofore, and it will be convenient for the reader that we shall consider the various departments of literature each by itself.

Poetry.—The bonds of continuity between eras, however unlike, are rarely if ever entirely wanting unless they are broken by some prolonged as well as violent political and social convulsion, such as we have remarked in the case of the Wars of the Roses; and the link that binds the poetry of the eighteenth century to that of the nineteenth is George Crabbe (1754–1832), in whose works both the form and the spirit which more or less pervaded English poetry from the time of Pope to that of Wordsworth are so manifest, yet with the modification produced by a tendency towards the contemplation of simple nature and of the reality of lowly life, as to win him the *sobriquet* of "Pope in worsted stockings." Crabbe's poems show close observation, a loving sympathy with nature, and not a little shrewd humor. Walter Scott (1771–1832), who followed soon after him, was very unlike him in the choice of his subjects and the style of his versification. Scott is the poet of chivalry and romance, and the story of his poems is always removed from modern times: he writes loosely and freely, but with great spirit and vivacity of movement; his fancy flies low, but his imagination is strong, and his love of nature and of the external signs of man's presence, as churches, castles, and buildings of all kinds, is very great. No poems ever received so quickly so large a share of public attention as his. They effected an entire change in the poetic taste of the time. After working his peculiar vein out, he turned his pen to prose fiction, and we shall meet him again in the ranks of the novelists. He was replaced in public favor, as a poet, by Lord Byron (George Gordon), (1788–1824), who, entirely unlike him in the spirit of his poetry, had some strong points of resemblance to him in the form and structure of his compositions. Like Scott's, Byron's principal poems are narrative, and have a freedom of versification and ease of style entirely opposed to the eighteenth-century manner. The heroic couplet and the epigrammatic period had disappeared from English literature, perhaps for ever. Byron's style is rich, sensuous, and brilliant; his motive, rarely high or pure. He is satirical, but because of a contempt for his kind rather than a hatred of what is bad and base. His descriptions, whether of natural objects or human action, are truly splendid; and in some passages, notably in his greatest work, "Childe Harold," he rises into the higher regions of poetry. But the tendency of his writings is debasing, less because of their sensual and epicurean tone than by reason of their derangement of the moral perceptions and their defiance of the moral sense. His heroes are unnatural combinations of incongruous qualities; his women mere compounds of beauty and unrestrained passions; and a gloomy and fierce egoism pervades his writing. But he is the richest in style and the most copious in fancy of all modern English poets. He was followed in public favor by his friend Thomas Moore (1779–1852), a poet of Irish birth, who wrote "Lalla Rookh" and "The Loves of the Angels," but whose real excellence was in lyric compositions. Moore's songs are charming in their tenderness, their lively fancy, and the sweet cadence of their verse, but they do not rise into the highest range of lyric writing. They smack of society, and have about them the odor either of the drawing-room or the dinner-table. Next in the galaxy of poets which distinguished the reign of George IV. we have to notice Thomas Campbell (1777–1844), a Scotsman by birth and a Celt by blood, who yet stands high in the annals of English literature. His "Pleasures of Hope" and "Gertrude of Wyoming" are his longest and his most ambitious poems. They are full of bright fancy, generous sentiment, and earnest humanity of feeling. But his lyric poems are his best, and they are of a very high order. They have the true fire and energy of the highest lyric school, mingling in rare combination fancy, passion, and reflection. His critical and biographical writings added largely to his literary reputation. Percy Bysshe Shelley (1792–1822) and John Keats (1795–1828) should be noticed here, although greater names are awaiting us. They both lived uncompleted lives, neither of them producing a work which attained the excellence of which they seemed capable. Shelley's life was one of revolt against society, and his longer poems are an utterance of his rebellious spirit. His minor poems express the exquisite tenderness and sweet fancies of a really lovely nature. Keats's "Endymion" and "Eve of St. Agnes," full of beautiful passages, lack the coherence and consistency of style requisite in poetry of a high order; but perhaps it may justly be said that he died too young for us to know the real calibre of his mind.

Among the poetical writers of this period these must be mentioned: the brothers Horace (1779–1849) and James Smith (1775–1839), the authors of the famous "Rejected Addresses," parodies or burlesques of subtle humor and inherent merit; Mrs. Felicia Hemans (1794–1835) and Miss Letitia E. Landon (1802–35), graceful and sentimental poetesses; Robert Montgomery (1807–55), the author of "Satan" and other religious poems; Theodore Hook (1788–1841), the author of irreligious poems and jests that belied his name; Joanna Baillie (1762–1851), known as the authoress of an elaborate series of "Plays on the Passions" which could not be played and are never read; and Sir Thomas Noon Talfourd, a common-law judge, whose one tragedy, "Ion," made a lasting reputation for himself, and for more than one representative of its title part, and is read with delight by those who eschew the theatre.

At this time appeared what was very loosely styled the Lake School of Poets, the first and chief of which was

William Wordsworth (1770–1850), whose poem, "An Evening Walk, addressed to a Young Lady from the Lakes of the North of England," was probably the occasion of the name given to him and his imitators. Wordsworth began to write in the old style, as appears by some poems written in 1786 which he preserved. But reaching manhood, he broke loose from this style, owing his emancipation chiefly to the influence of German literature, which then began to be much read in England. The reflective cast of this literature suited his mind, and he made himself the most meditative—we might almost say, the most ruminative—poet in English literature. He set out to reform English poetry, and his effort was toward an admirable end—simplicity and truth to nature. One means by which he hoped to attain his end was, in his own language, "by fitting to metrical arrangement a selection of the real language of men in a state of vivid sensation." He failed in accomplishing this end, which is incompatible with the requirements of any poetry; and one result of his efforts in this direction was the putting in some form of verse, generally a sonnet, almost every incident of an externally prosaic life. All his best works had their excellence (as his friend Coleridge said) in a treatment entirely at variance with his own theory, in conforming to which he produced of what was good only some short and simple poems of a remarkably picturesque beauty; but the rest of his verses, wrought out according to his theory, excited only the ridicule of his contemporaries, and have fallen into merited oblivion. Wordsworth in the best manifestation of his powers was a descriptive philosophical poet. He lacked passion, had no dramatic power, even enough to take himself out of himself, and his constructive ability was small. Of lyric power he had none whatever, and his versification has no peculiar charm. But in two styles of poetry he is without a superior, almost without an equal, in English literature. The first, which is almost peculiar to himself, is marked with a thoughtful and tender simplicity in the expression of the feelings of very humble people. It may be regarded as a very refined and elevated style of ballad-writing, the fidelity of the best old ballad style to the facts of nature being carefully preserved. The other style—and that in which the greater part of his best poetry is written—is speculative, deeply penetrative into the human heart and the relations of man with God and nature. It is grand, but when prolonged becomes somewhat wearisome. His sonnets, which are very numerous, are, with a few conspicuous exceptions, cold and dry, and seem, too many of them, to have been written under the pressure of a sense of duty. He wrote much, and we cannot here spare the room even to enumerate his important works. He was made poet-laureate in 1844, succeeding Southey, whom we next notice. Robert Southey (1774–1843) wrote much verse, but little poetry. What he might have produced had he concentrated his efforts we cannot tell. But he surely might have been one of the first of English prose-writers. The amount of writing that he did in verse and prose is really prodigious. But the essence of poetry is concentrated thought, or at least concentrated expression of thought; and that he lacked. He was in all things diffuse, although clear and simple and manly in style. His English is much admired by the best critics. But he was without originality even in style. Of all his verse not a line or a phrase has passed into the phraseology of common life except one—"deeply, darkly, beautifully blue"—which owes its circulation to Byron's having quoted it. Of all his works only his rambling, humorous "Doctor" is now read; but he was one of the most conspicuous literary personages of his time.

Younger by a year or two than Southey, and his friend and Wordsworth's, was Samuel Taylor Coleridge (1772–1834), a man who, if he had been content with being only a poet, would have been a poet of the highest rank, excluding the three who stand together—Homer, Dante, and Shakspeare. Coleridge began life by being an enlisted dragoon; he next projected a Utopian republic on the banks of the Susquehanna; next he became a Unitarian preacher; he afterward turned Trinitarian and Tory; and he passed the remainder of his life writing and talking with a marvellous mingling of grandeur and subtlety, but leaving nothing complete except a few short poems. He was one of the last of the great talkers, the very last being Macaulay; and like him he spoke soliloquy. Referring to his Unitarian period, he once said to Lamb, "Charles, did you ever hear me preach?" "Samuel," replied the stuttering wit, "I n-n-never heard you do anything else." All this is characteristic of the man. He was a grand intellectual torso, or rather a succession of unfinished clay models of what he might have been. The author of "The Ancient Mariner," of "Christabel," of "Love," of "Genevieve," of the "Hymn to Chamouni," of "The Devil's Walk," of the lines upon "Cologne," and the translator of "Wallenstein," had the capacity of a great poet of very varied powers. But he was beset by the demon of criticism, that foe of the creative faculty; he could not resist the temptation to wander away into the fields of metaphysical speculation; he sapped his mind and shattered his body with opium-eating; and so he ended his life, a splendid wreck, leaving the wealth that he bore scattered upon the shores of immortality.

Mentioning Samuel Rogers (1763–1855), the banker-poet, the author of the "Pleasures of Imagination," a writer who formed himself rather upon the eighteenth-century models, and who, as Byron said, "when he was delivered of a couplet took to his bed and tied up his knocker;" and Thomas Hood (1798–1845), one of the most charming of our humorous poets, and one who combined his humor with a pathos peculiarly his own, whose "Song of a Shirt" and "Bridge of Sighs" have touched, and will ever touch, all true hearts with sadness,—we pass to poetical writers of our own day.

Chief among the elders of our living poets are Bryant, Longfellow, and Tennyson. William Cullen Bryant (born 1794) first commanded public attention by a poem, "Thanatopsis," written when he was nineteen years old—a grand monody upon the end appointed for all living, the inspiration of which was perhaps caught from a passage in "Measure for Measure," and which has taken a place among the classic poems in our language. After accomplishing threescore and ten years he has made a translation of Homer which disputes the palm of superiority with all its predecessors. Between these periods of a laborious life he has written not much poetry, but none unworthy of the fame he won so early and has sustained so late. In purity of style, in the finish of his verse, in the elevation of his thought, and in his loving portraiture of nature he is unsurpassed among living poets. His writings make us wish that poetry had been the business and not the mere adornment of his life.

Henry Wadsworth Longfellow (born 1807), on the contrary, has passed his life in the pursuits of the higher literature. His two earliest books, "Outre Mer" and "Hyperion," were prose, but the prose was that of a man of poetical temperament. Then came the "Voices of the Night," which at once commanded the attention of the whole English-speaking public, and which have been translated into German and into other languages. Since then he has given the world many volumes of poetry which have enjoyed as great a popularity in Europe as in America. Mr. Longfellow's poetry has the rare quality of addressing itself directly to the minds and hearts of all men. High and low, educated and uneducated, all acknowledge its charm. Singularly refined in his every utterance, he is the most popular of living English poetical writers. His poems are galleries of characters uttering sentiments that sink into the general heart. To his original works he has added a translation of Dante, the singular fidelity of which to the original in thought and in form shows no less his mastery of his own tongue than his thorough and subtle knowledge of that of the great Florentine poet.

Alfred Tennyson (born 1809), who succeeded Wordsworth as poet-laureate, has since the death of his predecessor held the first place among living British poets. It would seem in his case almost that the poet was made, not born, for his first volume, published in 1830, gave no promise of his future fame; and it was not until twelve years afterward, when Longfellow had published his "Voices of the Night," his "Ballads and Other Poems," his "Poems on Slavery," and had in press "The Spanish Student," by which his style of versification and the character of his thought were fully displayed, that Tennyson published his second volume, "Poems chiefly Lyrical," in which the "Morte d'Arthur" and "Locksley Hall" gave unmistakable indications of his genius. These facts dispose of the assertion, which has been unwarily made, that the New England poet is an imitator of his British contemporary, a somewhat younger man and a very considerably later poet. Since the publication last mentioned, Tennyson's poetic faculty has grown greatly, and with it his fame. Tennyson is eminently a poet whose powers have been developed, almost made, by discipline and by culture. Like Wordsworth, he has held himself apart from the world, consecrating his life to his Muse. His style is elevated, pure, and deeply thoughtful. He deals with the great problems of the human soul—but incidentally, none of his works having a distinctly metaphysical or even a moral aim. His "In Memoriam" is in this way very characteristic of his mind, and with his "Idyls of the King" presents the highest manifestation of his powers. He always writes with a high aim, but always shows a consciousness that he is doing so. The deficiency of his poetry is in spontaneousness and energetic utterance. He rarely catches "a grace beyond the reach of art." But some of his lyric

poems, like the one beginning "Break, break, break on thy cold gray rocks, O Sea!" have an exquisite charm of sentiment.

If the dramatic writing of the day were worthy of classification as literature, Robert Browning (born 1812) should be regarded as at the head of the dramatic poets of the day. This place would be his, not so much by virtue of his plays as because all that he writes is imbued with the purest and highest dramatic spirit. He is not only the greatest English dramatist of the age, but the greatest since Shakspeare. He has that power so admirable, so rare, of creating living personages whose characters become known to us not by description, but by their own actions and utterances. In these characters he entirely loses his own identity, and even, it would seem, his own consciousness. He thinks their thoughts and feels their feelings. This is true in what seem to be descriptive poems; and the well-chosen names of two of his volumes, "Men and Women" and "Dramatic Lyrics," show a consciousness on his part of this power. His versification is often rough, his style careless, his thought involved; but those who understand him forgive these defects (which he sometimes compels into charms, if not into beauties) for the delight they take in his rare dramatic genius. He married Elizabeth Barrett (1809–61), the most eminent of English poetesses, whose "Portuguese Sonnets" (in which the love crowned by that marriage is covered by a very transparent veil) are admirable for fervor and freedom of utterance, and whose "Aurora Leigh" is in fact a novel of Society wrought skilfully into a charming narrative poem.

James Russell Lowell (born 1819) and Matthew Arnold (born 1822) are exemplars of the union of the poetical and the critical faculty in an uncommon degree. No one can read Mr. Lowell's "Legend of Brittany," his "Sir Launfal," his "Commemoration Ode," and his minor poems without wishing that he had given his life to the development and the perfection of the great natural poetic gift which they indicate. As a humorist he has few equals, and he is most widely known by the "Biglow Papers," a series of humorous satirical poems in the rustic New England dialect, of which Lowell is a perfect master. His critical essays, collected in "Among my Books" and "My Study Windows," are marked by searching independence of thought and the fruits of a wide range of reading, enlivened by touches of his rare and racy humor. Of Matthew Arnold's poems, his dramatic "Sohrab and Rustum" is the finest exhibition of his power in this direction. It has the true antique grandeur, with the antique simplicity and directness. His essays and critical writings, which are numerous, are marked by unusual subtlety of thought and an exquisite finish of style. He is perhaps the most polished living writer of English.

Algernon Charles Swinburne (born 1837), the most prominent, if not the most admirable, of the younger English poets, first commanded attention by his poetical drama, "Atalanta in Calydon," which is remarkable for its exquisite fancy, its wealth of language, and its strong infusion of the old Greek spirit. His other dramatic poems, although not equal to this, delight admirers of strong passion and unreserved utterance. A volume of "Poems and Ballads" exhibits the same qualities in a greater degree, clothed in a versification the external richness and strength of which compel an admiration sometimes unwillingly given to such exhibitions of nakedness of soul and body.

But there are two kinds of nakedness, both of soul and of body: the purer kind never was seen in a more alluring form than in the poems of William Morris (born 1833), whose "Jason" and "Earthly Paradise" have placed him high in the second rank of English poets. Mr. Morris goes to the legends of ancient Greece and of the Middle Ages for his subjects; and he tells these old tales with such vividness of imagination, such picturesque and sensuous richness of description, and such sweet simplicity of feeling that he renews and freshens all their old beauty and adds to it a charm of his own. His versification is remarkable for its easy flow and for the luscious richness of its sound. But his great strength lies in his imagination. He sees before him the subject of his verse. As a narrative poet he has no superior or equal but Chaucer, of whom he professes himself the scholar; and thus, in our day at least, we see the cycle of English poetry returning to the point whence it started.

Of the poets of minor fame we must mention Whittier, who has produced some fine—perhaps the purest modern—examples of true ballad poetry—high praise, for the true ballad, one of the most charming forms of lyric composition, is, in modern days, among the rarest of poetical productions; and the author of "Barclay of Ury," "Maud Muller," and "Barbara Frietchie," always pure, fervid, and direct, will be remembered when many a more voluminous and ambitious writer is forgotten; T. W. Parsons, the master of a true and strong poetic utterance; Jean Ingelow; Bret Harte, whose humorous poems in dialect have qualities regarded as peculiarly "American;" Bayard Taylor, who has made the best translation of "Faust;" Richard H. Stoddard, George H. Boker, Edmund C. Stedman; and Walt Whitman, who amid heaps of commonplace rubbish in fantastic form has dropped some lines weighted with thought and true feeling.

The principal dramatists of the present century are Sheridan Knowles, Dion Boucicault, Tom Taylor, and Robertson, but no one of them has written a play which has any value except upon the stage. In the English language dramatic literature seems to have ceased to exist. Richard Brinsley Sheridan (1751–1816), belonging partly to the last century and partly to this, is the last of the dramatic school. But even his comedies are comedies of wit, not of character, and the wit is always that of Sheridan, not of the personages who utter it.

Novels.—In no department of literature has the increased intellectual activity of the present century been so copiously manifested as in that of prose fiction. The writers of novels are to be numbered now-a-days by the hundred. Merely mentioning the names of Hannah More (1745–1833), the authoress of "Cœlebs in Search of a Wife" and other writings of a pietistic-social purpose; William Beckford (1760–1844), whose "Vathek," originally written in French, does not for its merit deserve a notable place in English literature; Anne Radcliffe (1764–1823) and Matthew Gregory Lewis (1775–1818), (called "Monk" Lewis, from the title of his most celebrated work), both of whom revelled in horrors and mysteries; and the two sisters, Jane (1776–1850) and Anna Maria Porter (1781–1852), the priestesses of the goddess of sensibility—all of whom belong rather in spirit, as they do much in time, to the eighteenth century—let us pass to the consideration of the later and stronger writers of fiction, only the most eminent and characteristic of whom can be noticed here. The great novelist of the century and of our language—and, it is not too much to say, of the world—is Sir Walter Scott, who, as we have seen, holds also so high a place among its poets. "The Waverley Novels," so called from the title of the first one of the series, are chiefly historical—that is, their plots are interwoven with historical incidents, and some of their principal personages are figures taken from history. In correctness of historical detail, as also in correctness of style, they are open to adverse criticism. But trifles of that kind are, or ought to be, disregarded by even the best-informed and most cultivated readers as they are borne onward upon the strong, steady stream of the story. Scott was simply the greatest writer of stories that ever lived. His imaginative realization of his personages, and his dramatic evolution of their characters and management of their intercourse with each other, are inferior only to Shakspeare's, from whom to him, in imaginative writing, criticism may take one great leap. No other writer but Shakspeare has filled the world's memory with such a throng of living figures, so varied in their types, so lifelike and real-seeming in their action. He spends little time in analyzing motives and in dissecting character; but with strong clear touches, every one of which has meaning, he places the man or the woman before us, and we know them, as we know our friends or our enemies, for ever after, and at once we become interested in their feelings, their actions, their experience, and their fate. Scott is a singularly healthy writer. There is hardly a morbid passage or an injurious one in any sense in all his works. We rise from them refreshed, delighted, invigorated, elevated. In narrative power, in truthfulness, in picturesqueness, in lifelike action, in the clear management of a complicated action, in united strength and delicacy of portraiture, in grandeur of movement, in humor, and in charm of style he is without a rival. Miss Jane Austen (1785–1817), who followed him as a younger contemporary, is one of the best of English domestic novelists. Her works will always be read for their intrinsic interest and as faithful and pleasing pictures of the society of her time. George P. R. James (1801–60) was an imitator of Scott, and although a prolific writer and a favorite with the public of his day, he has shared the fate of all imitators, and is now little read. But the author of "Philip Augustus" and "One in a Thousand" was a novelist of no mean powers. Edward Lytton Bulwer (1806–74), afterwards Lord Lytton, in his first novel, "Pelham," introduced to the world what is distinctively known as the novel of fashionable society. He afterwards extended his field and wrote historical novels, sentimental novels, novels descript and nondescript. A man of high culture, of various acquirements, and a writer of considerable power, he commanded for many years the admiration of a wide circle of readers. But he was in no way original; his sentiment was equally

false and excessive; his style was artificial; he had no dramatic power; and his personages have no true life or character, but are bundles of clothes with something in them that talks what Edward Bulwer thought. No one of them lives except Pelham, a typical high-class dandy of the latest Georgian era. His best works are "The Caxtons" and "My Novel," written in imitation of Sterne.

Benjamin Disraeli (born 1805)—the son of Isaac Disraeli (1768–1848), an accomplished Hebrew who was converted to Christianity, and who is widely known as the author of "The Curiosities of Literature," "The Amenities of Literature," and "The Calamities of Authors"—is the author of several novels, the earliest of which is "Vivian Grey" (1825) and the last "Lothair" (1870). His works are brilliant, and have always commanded attention, but they are fantastic, extravagant, and untruthful as representations of human nature or of society at any time or in any country. Most of them have a political or a social purpose, and are believed to contain portraits of contemporary politicians and other persons of distinction. But "Henrietta Temple" has been regarded by some critics as one of the most natural love-stories ever written. His last book, "Lothair," is directed against the proselyting policy of the Roman Catholic Church. His writings indicate a strong prepossession in favor of the Hebrew race. His chief distinction is in the field of politics. He has been twice chancellor of the exchequer, and is now premier.

Charles Dickens (1812–70), a man not of high but of singularly original powers, next appeared upon this field. He was a humorist, and found congenial subjects among characters of low, or at least of humble, life. Of these his caricatures—for he rarely drew except to caricature—are infinitely amusing. His attempts to rise above this plane were, with one notable exception, "The Tale of Two Cities," conspicuous failures. His sentiment is generally exaggerated, and his pathos often false. But as a humorist, pure and simple, he is unrivalled in the present generation. William Makepeace Thackeray (1811–63), also a humorist, was a writer of a very different stamp. His novels are satires upon society. But his style is pure, his satire delicate, his caricature little exaggerated, and his pathos is true and often profound. His personages generally belong to the cultivated classes of society, and his representations of gentlemen and ladies, both as to their manners and their motives, are always worthy of admiration. The author of "Vanity Fair," "Pendennis," and "Henry Esmond" has a high and a permanent place among English writers of fiction. Charles Kingsley (born 1819) is the author of novels of very considerable merit, among which are "Alton Locke," "Yeast," and "Amyas Leigh."

Among the many women of the day who have written novels, Charlotte Brontë (1816–54), the authoress of "Jane Eyre," holds a conspicuous place. Her few works are chiefly remarkable as giving, with great subtlety of perception and boldness of utterance, the woman-view of man's character, and as to women their view of themselves in relation to man. Very introspective and analytic, they dissect motives with a hand at once bold and delicate. In this respect, however, as in all others, she must yield to the writer who appeared under the name of "George Eliot," but whose real name was Marian C. Evans (born about 1820), and who is one of the most conspicuous persons in English literature of the present day. "George Eliot's" constructive power is small; she is not a great teller of tales. In her subtle analysis of character and revelation of motives she allows the movement of her story to lag; she crowds her canvas with too many figures, all painted like miniatures, until she and the reader both begin to forget the main purpose in hand. To this criticism, however, her earlier sketches, her first novel, "Adam Bede," and above all "Romola," are in a great measure exceptions. "Romola," as the history of two lives, and in the revelation of character and the motives—the unacknowledged and almost self-unknown motives—of its principal male character, Tito—is a marvelous work of art. "George Eliot," like the generality of female writers, is most successful in describing what she has seen. Her personages are studies from life, but she has a vivid imagination and great dramatic power. Her views of life and of human nature are gloomy and depressing. Her style is in all respects admirable.

Charles Reade (born 1814) has written many novels which by their vividness of portraiture, their vivacity of movement, and their humor have taken a firm hold upon the public. Whatever the nicely fastidious may think of the taste of much that he has written, even they cannot fail to be interested in the fortunes of his personages. His effects are theatrical, and sometimes seem as if they were contrived for the stage. He leaves little impression of reserved power. His best works are "Christie Johnstone," "Peg Woffington," and "The Cloister and the Hearth;" the last an historical novel which needed only condensation to have taken a high place among works of that class.

To prose fiction America has contributed little, and of that little the works of but one author are of a very high order. In the last century, Charles Brockden Brown (1771–1810) wrote novels which have some power of enlisting the attention, but the morbid tone of which made them repulsive, and they have been wisely allowed to pass into oblivion. James Fenimore Cooper (1789–1851) attained a greater and more enduring celebrity. This was chiefly, however, because his scenes were laid in frontier life, among hunters, trappers, and Indians. They pleased those whose taste delighted in adventure, and in Europe they commanded attention because they were regarded as peculiarly "American." As tales of adventure they are interesting to those who are not fastidious as to the truthful seeming of what they read; but they have no value as studies or pictures of human nature. The characters are impossible, and the style is poor, mean, and unpolished. They are chiefly adapted to the tastes of very young men and boys. Cooper's sea-novels are of greater merit, if not of a higher order. After Cooper there was no American novelist worthy of special notice until the appearance of Nathaniel Hawthorne (1804–64), whose "Scarlet Letter" at once commanded the admiration of the whole literary world. Hawthorne was a writer of the most marked originality and at the same time of the highest finish in style. His novels are highly dramatic; but their dramatic power is as unlike that of Scott's, for instance, as can be. He deals with the inner life of his personages. We see them indeed, but chiefly we live their lives. His death cut short what promised to be a brilliant career, but he left enough behind him to secure an enduring fame. Edgar Allan Poe (1811–49) produced no novel, but as a writer of tales, the strange incidents of which he had the singular power of making seem not only probable, but actual and real, he attained distinction at home and abroad. He writes like a gifted reporter of extraordinary and incredible scenes which pass before his eyes. With him it is difficult to draw the line where the possible ends and the impossible begins. His fanciful poems and his trenchant criticism added to his reputation, but he does not take a place among those who have nature as a model. Probably no modern work of fiction was so widely read as Mrs. Harriet Beecher Stowe's (born 1812) "Uncle Tom's Cabin;" but the interest which it excited was due chiefly to the sensitiveness of the public mind all over the world upon the subject of slavery in the U. S. The same lady's other novels, although superior to that which made her known, have failed to receive anything like equal marks of public favor.

The novel of modern society has attained what would seem to be its highest and most perfect development in the voluminous works of Anthony Trollope (born 1815). His discernment of character is subtle and true; his appreciation of social relations and of their effects upon external and internal life has never been equalled, and it would seem cannot be surpassed, because it is perfect. He is not specially humorous, or satirical, or sentimental, or sensational; and yet humor and satire and sentiment and sensation all appear in his novels, simply by their being so true a reflex of individual and social life. Reading one of his novels is like being a secret observer of the lives of other people—so much so that it sometimes carries along with it a sense of shame. We feel as if we had not a right to be thus watching our neighbors, and following them into the inmost recesses of their souls as well as their houses. Mr. Trollope's effects are produced only by the choice of characters and the grouping; the charm of his stories is that of simple nature, but nature as it is seen in the most highly cultivated and complex society. If they are ever tame and commonplace, it is because that society is tame and commonplace; and their many characters which are noble, and their many passages which are colored with the warm hues of strong or tender feeling, show that all that is artificial and conventional in modern society does not repress, but sometimes tends even to heighten and to quicken, the emotions of unchanging human nature. In the completest contrast to the novels of this author are the vivid and picturesque sketches of California life, in prose and verse, of Francis Bret Harte (born 1831), who has rapidly attained the reputation of being the first writer of fiction whose works are marked by a peculiarly "American" tone and atmosphere; and possibly there may be something in them of this kind which is not due only to their characters and the social conditions which they represent. However this may be, their interest is peculiar and their humor delicious.

Thomas Hughes (born 1823) became celebrated as the author of "Tom Brown's Schooldays" and "Tom Brown at Oxford," two novels written for very young readers; but, like all good books of that kind, they were full of interest

for those of riper years. The manliness of tone in these books, their sound morals, far removed from all priggish pretension to goodness, and the thorough understanding of boy-nature which they show, have made them classics in their kind. In style they are as simple and as manly as they are in spirit. Charles Shirley Brooks (1815–74) should be mentioned as a society novelist of very considerable powers; and William Wilkie Collins (born 1824) as the author of tales remarkable for their striking and well-contrived but not very probable plots.

Among the crowd of novelists of the day whose very names cannot be mentioned except in their aggregate form of Legion, that of William Black is rising into distinction. The author of "A Princess of Thule" can hardly fail to take a high place in fictional literature. The most vivid and truthful presentation of American social life in the great centre of its wealth and commerce that has yet appeared is "Never Again" by William Starbuck Mayo, M. D. (born 1812), a book of which the humor, the knowledge of the world, that mark its every page will cause regret that it is, and will probably remain, its author's only novel. George William Curtis (born 1824) has also written one novel, "Trumps," but he will rather be remembered as the author of "Prue and I," a series of confessions of a simple-minded old bookkeeper of exquisite tenderness and sweetness of sentiment, and of the "Potiphar Papers," a burlesque of New York society, and of his "Howadji" travels, in the style of Kinglake's "Eothen."

Essayists and Miscellaneous Writers.—Few tasks are more difficult than the classification of books and their writers; and as to the latter, those of the present century are in many cases so various in the subjects which they respectively treat that this difficulty increases as we approach our own day. But turning to the past generation, where shall we place William Cobbett (1762–1835), who wrote upon politics, gardening, language, and what not? It is chiefly as a political essayist, however, that he will be remembered. His writings show strong common sense, strong prejudices, independence of thought, set forth in a direct, manly, incisive style. William Godwin (1756–1836) wrote a novel, "Caleb Williams," the fame of which still lives, but his chief distinction was that of a political essayist and historian of robust mind and strong liberal tendencies. His wife, Mary Wollstonecraft (1759–97), by her "Vindication of the Rights of Woman" took the lead in a movement which seems to be still advancing. Charles Lamb (1775–1834) will be always read, and always loved, for the gentleness of soul and the exquisite humor, sometimes falling into mere personal whim, which appear in his "Essays of Elia" and his correspondence. To him there could not be a stronger contrast than Walter Savage Landor (1775–1864), who had all the virtues and most of the faults peculiar to the Anglo-Saxon race, and embodied them in his writings, although his peculiarities of temper kept him so at war with his kindred, and even his country, that he passed most of his life in voluntary exile. His "Pericles and Aspasia," "Imaginary Conversations," "Last Fruit off an Old Tree," and "Dry Sticks" show a wide range of learning and strong critical sense, but narrow sympathies, and an absence of that great lubricator of the friction of life—humor. John Wilson (1785–1854), although he wrote some poetry, is remembered for his "Christopher North" papers upon literature and sporting subjects, which were published in "Blackwood's Magazine," of which in its earlier years he was editor. His critical taste was sound, but much of his writing is mere animal spirits put on paper, and he was chief of a school all of whose pages reek with the fumes of whisky and tobacco, which cannot, however, entirely becloud their strong sense and their scholarship. For whisky and tobacco Thomas De Quincey (1785–1859) substituted opium, to which we owe his "Confessions of an Opium-Eater," and perhaps its effects may be traced in "Sursum Corda" and in many of his subsequent voluminous writings, which are crowded with the evidences of a wide range of desultory scholarship, with subtle criticism, rich fancy, and a peculiar humor, all embodied in a style of remarkable richness and splendor. William Hazlitt (1778–1830) was the nineteenth-century embodiment of the ideal literator. He lived from early manhood until his death, not very happily, upon the miscellaneous products of his pen as a contributor to various periodical publications of his day. He was consequently able to do little as we may be sure he would have liked and was able to do it. But as a critic of literature and art and of society he holds a high place, which he owes in a great measure to his manly and thoroughly English style. James Henry Leigh Hunt (1784–1859), another writer of the same sort, has less force, but is always graceful and pleasing. But the great modern master in English of grace and ease, and of a lambent humor much like that of Addison, is Washington Irving (1783–1859), whose "Sketch Book," "Knickerbocker's History of New York," and "Legends of Sleepy Hollow" do more to secure his enduring fame than most of his more ambitious works, including his "Life of George Washington." Notably unlike Irving in every way is Thomas Carlyle (born 1795), whose style is rugged and whose humor grim, but who is a critic of the first class, and whose "Sartor Resartus" is a subsoil plough driving deep beneath the surface conventionalities of society. A like purpose prevails in his "Latter Day Pamphlets" and "Hero-Worship." It is to be remarked that Carlyle's peculiar style—so peculiar that it has been called "Carlylese"—does not appear in his earlier works. Mr. Carlyle the reformer appears as a scornful, scourging critic, and in that spirit he has written his historical works, "The French Revolution" and "Frederick the Great." To him Ralph Waldo Emerson (born 1803) has been not very happily compared. The purpose of the two writers may be the same, but their manner is entirely different. Emerson has the calm observance and the serene thoughtfulness of a philosopher, and he shows a strong love of external nature of which Carlyle seems scarcely conscious. His style is aphoristic and epigrammatic; but although both his prose and his poetry are full of wisdom, they not unfrequently degenerate into commonplace, or what would be commonplace were not what is common in it used with such a keen knowledge of its significance and its relations. Perhaps Caroline Elizabeth Norton (born 1808), a miscellaneous writer who inherited some of the talent of her grandfather, the great Sheridan, should not be left unmentioned.

Among the wits of the generation which is passing away two were pre-eminent—Sydney Smith (1771–1845) and Douglas Jerrold (1803–57), but their wit was almost their only point of likeness. Jerrold's wit was a scourge, while Sydney Smith's was the genial laughter of a lover of his kind. His essays touch many of the most important topics in which men of these times are interested, and they are loaded with sagacity. His style is remarkable for its clearness and manly dignity. Another wit whose wisdom is greater than his wit is Oliver Wendell Holmes, M. D. (born 1809), of whose writings his "Breakfast-Table" books—the "Autocrat," the "Poet," and the "Professor"—exhibit his mind and his style at their best. They present a curious and careful study of that variety of human nature which is found in the New England of the nineteenth century, and are threaded through and through with gentle satire. The study of human follies and human weakness and of the conventional forms of modern society which took Holmes to the breakfast-table and Sydney Smith to the dinner-table, drove Henry David Thoreau (1827–62) to a hermit's life, in which he lived in a cabin of his own building, chiefly upon beans of his own growing. He studied birds and beasts and inanimate objects for the purpose of reflecting severely upon man. But his love of nature was genuine, his love and knowledge of literature great, and his own style beautiful. He cannot be read without forgiveness for his gentle mistaken misanthropy. Arthur Helps (born 1817) has won for himself a peculiar, and if not a very high, we may be sure a long-enduring, place in literature. Without the least affectation of singularity, either in the style or the plan of his works (all of the most important of which are in the form of essays with dialogues upon them), with little that is strikingly new in his thought, he commands the respectful attention of a large circle of the very highest class of readers. This he does by the very clear and earnest way in which he brings up and presses home half-forgotten truths which concern the daily life of all cultivated people. We may think that we have heard what he says before, but we are almost sure to think that we never heard it said so well. He presents homely common sense in the most elegant dress. He has written two novels, "Realmah," over which his Friends in Council entertain themselves and his readers with wise and witty chat, and "Ivan de Biron." Among other writers of this class in America even such a sketch as this must notice Donald Grant Mitchell (born 1822), a polished satirist of society and an observant critic of rural life; Thomas Wentworth Higginson (born 1823), whose essays are strong protests against physical and mental weakness; Edward Everett Hale (born 1822), whose sermons, essays, and sketches all show a strong, clear, subtle mind, a lover of freedom, and a Christian of the Broad Church; and William Dean Howells (born 1837), whose pictures of European and New England life are marked with penetrating observation, humor, and a charming grace of style.

Criticism of the Arts of Design, like those arts themselves, sprang up late, and at first grew feebly, among the English-speaking peoples. George Hogarth's (1697–1764) "Analysis of Beauty" and Sir Joshua Reynolds's (1723–

92) "Lectures," although not without suggestions of some value, are chiefly distinguished as the works of eminent painters. And Burke's "Essay on the Sublime and Beautiful" is all awry from its purpose. Its very style lacks all its author's peculiar charm. Rev. Archibald Alison (1757–1839) wrote "Essays on Taste" which promoted culture in this respect, but which are now rarely referred to; but Sir Uvedale Price's "Essays on The Picturesque," published in 1810, may still be read with profit, and have since been reprinted. Mrs. Anna Jameson's (1797–1860) works upon Christian art contain much that is valuable, both of history and criticism. But it was not until the appearance of John Ruskin (born 1819) that we had a truly subtle, profound, and thoroughly qualified critic of fine art—one who to his critical perceptions joined the ability to communicate them with beauty and impressiveness of style. Mr. Ruskin's chief distinction as a critic is that he never writes without making his hearers think, even when they smile at his utopian theories of society and of political economy. James Jackson Jarves (born 1818) has written with knowledge, thoughtfulness, and honesty about art, and particularly ancient art; and Philip Hamerton is a pleasant and safe drawing-room companion to the lover of art who does not care to be profound.

Criticism has been raised to a special branch of literature during the present century, toward which the establishment of the great British Reviews, the "Edinburgh," the "London Quarterly," the "Westminster," and in America the "North American," contributed largely; their influence and example have been such that now no magazine or newspaper of the first class, either in Great Britain or America, appears without such critical reviews of literature in all its branches, of art, and of science, as fifty years ago were produced nowhere, and which, with allowance for much ignorance, presumption, and bad taste, on the whole guide the public mind aright. In this department of literature many of the writers who have already been mentioned attained distinction.

Of those not hitherto mentioned, Lord Francis Jeffrey (1773–1850), William Gifford (1757–1826), and John Gibson Lockhart (1794–1854) deserve special mention. They were all severe, as well as able and generally honest, in their criticism, and did much toward the formation of the public taste in the early part of the century. Henry Hallam's (1778–1833) "Literature of Europe" contains a mass of various learning and generally sound critical opinion. It is, and will probably remain, the standard work upon its subject in the English language.

Philology, using the word in its widest sense, includes all writing upon language, even the well-known grammar of Lindley Murray (1745–1826), the American Quaker who for so long gave the law of the construction of their language to all English-speaking people. But comparative philology, which alone is worthy of the latter half of its name, is the product of the present century, and had its rise in the discovery and study of the Sanscrit language, the oldest known representative of the speech of the Aryan or Indo-European peoples. This discovery, which is due to Sir William Jones (1746–94), established a connection between the modern world and that of pre-historic times, and revealed the bond which binds together all the Indo-European peoples. But before this discovery an analytic philologist (or etymologist) of great ability, John Horne Tooke (1786–1812), had appeared in England. His "Diversions of Purley," although not without errors, is a monument to his learning, sagacity, and fine linguistic sense. In the last and the present generation Joseph Bosworth (1788) has investigated the field of Teutonic and Scandinavian languages; George P. Marsh (born 1801) has philosophically recorded the growth of the English language and its literature; Robert Gordon Latham (born 1812) has, with a profound and a vast range of knowledge, developed theories of ethnological philology, has dissected the English language, written its grammar on philological principles, and completed an English dictionary based upon Johnson's. William D. Whitney (born 1827) has pushed his investigations of the Oriental languages and of the wide field of the higher philology to what seems almost the verge of attainable knowledge; James Hadley (born 1821) has shown that he might have been his rival; Max (Frederick Maximilian) Müller (born 1827) has delighted and stimulated all students of philology by his brilliant generalizations in the "science of language" in its broadest sense; March has produced his great Anglo-Saxon grammar; and Trench and Farrar and Garnett and Helfenstein and Craik and Skeat and Childs have distinguished themselves by works of narrower scope, but hardly of less interest. The Early English Text Society, under the management of the able and indefatigable Frederick J. Furnivall, has published a great mass of well-edited English writing of the twelfth, thirteenth, and fourteenth centuries, and made accessible to eager students materials which they are using for the elucidation of the philology of their mother tongue.

History.—In no department of literature has a greater change been manifest during the present century, both in form and in spirit, than in history. This change—the result of the combined influences of the comparative system introduced by Niebuhr, of the strong tendency toward a positive or scientific treatment in all branches of intellectual endeavor which rest in any way upon facts, and of the increased appreciation of the value of the minutest matters of record which show the intellectual, moral, and social condition of a whole people, the middle and lower, as well as the noble and educated classes—has caused the historians of the modern school to extend their researches, to enlarge their plans, and to endeavor to portray upon a vast field not only the great vicissitudes of nations and the eminent individuals who controlled, or seemed to control them, but the whole political, moral, and social life of the people and the periods whose stories they undertake to tell. Hence, histories are now at once more fragmentary and more minute than they were of old. These changes, however, do not appear in the earlier historical writings of the century; but they increase as it advances.

English History.—Dr. John Lingard (1771–1851) wrote a history of England down to the abdication of James II., which is valuable for its research, the mass of facts accumulated, its calm tone, and its skilful arrangement. But it was written from the Romanist point of view, with a Romanist purpose; and its value is seriously impaired for Protestant readers by its skilful perversions and suppressions of fact. Sharon Turner's (1768–1847) "History of the Anglo-Saxons and of England during the Middle Ages" is the only thorough and systematic presentation of its subject in the English language. Trustworthy as to fact, it is deformed by an ambitious, involved, un-English style. Lord Mahon (Earl Stanhope, born 1805) must be mentioned as the faithful and thoughtful, although somewhat spiritless, historian of England from 1718 to 1783. Sir James Mackintosh, who failed to do all that his unquestioned abilities gave reason to expect, produced a compact "History of England" (3 vols., Lardner's "Cyclop.") remarkable for a clear and philosophical treatment of political and constitutional questions. But the great constitutional historian of England is Henry Hallam (before mentioned). He is learned, thorough, candid, and, although liberal in tendency, judicially calm, as becomes his subject. His "History of Europe during the Middle Ages" has the same qualities, but lacks picturesqueness of presentation. The subject of the constitutional history of England has been ably continued by Sir Thomas Erskine May (born 1815). Sir Archibald Alison (1792–1867) is the author of a "History of England" from the beginning of the French Revolution to the Restoration of the Bourbons, which has the great value due to an industrious collection and systematic arrangement of facts by an almost contemporary writer. But it is diffuse, prolix, and deformed by a style both pretentious and ungraceful. It is best read in his own abridgment of it. Thomas Babington Macaulay (1800–59) produced, in his "History of England from the Accession of James II.," the most striking and picturesque historical work of the century. Written with strong partisan prejudices, if not with a partisan purpose, it is filled with masses of moral light and shade, and must be read with corresponding allowance as to facts and its representation of individuals. But in its grouping of facts, in its pictures of social life, and in the splendor and the graceful ease of its style it is without a rival in our literature. The great research upon which it was founded and the minuteness of its picture-painting made it impossible for the author to bring it down, as he had intended, to a period within the memory of living men. Its five octavo volumes cover a period of only fifteen years. With its author's essays upon the characters of Bacon, Milton, Addison, Walpole, Johnson, Byron, and Hastings, it forms a body of historical writing of almost unequalled splendor and interest. James Anthony Froude (born 1818) has produced a very valuable history of England during the times of the Reformation. His investigations have led him to take new views of the characters of Henry VIII. and Elizabeth, which the authorities quoted by him seem to support; but upon the much-vexed question as to the characters of the two Maries of Scotland and of England he ranges himself at the head of their condemners. On the history of Ireland he has also written vigorously and after much original research. Edward A. Freeman (born 1823) is the author of a "History of the Norman Conquest" written from an entirely new point of view, in which he presents a philosophical appreciation of the causes which led to the invasion, of the condition of insular and continental society at that period, and of the social and political conse-

quences of the conquest. Its great merit gave him at once a high position in historical literature. The various biographical works of Mr. John Forster (born 1812) have so marked an historical bearing that he deserves honorable mention as a writer in this department.

Continental History has been illustrated by two English writers of eminent ability. Thomas Carlyle's "History of the French Revolution" is rather an expression of the spirit of the time of that great event than a record of its facts, a knowledge of which is almost assumed by the writer. But it is perhaps the most complete and characteristic manifestation of its author's peculiar genius. His "History of Frederick the Great" is truly historical, and presents new results of original research. It is written in "Carlylese," and is full of fantastic and grimly humorous passages, but its truly historical value is nevertheless very great. John Lothrop Motley (born 1814) has taken the highest position as the historian of the Netherlands and the Dutch Republic. To the results of patient research and logical analysis he adds the attraction of a fervid style and an almost enthusiastic love of his subject.

The History of the United States has been written by George Bancroft (born 1800) with a minuteness of detail which often produces the impression that he looks at small and commonplace occurrences through the magnifying and glorifying medium of their consequences. His style may also be regarded as often too ambitious for the subject immediately in hand. But as a whole his work is worthy of the admiration it has received and of the authoritative position it has attained. Richard Hildreth (1807–65) wrote his "History of the United States" in a style directly opposite. It is cold, dry, unpicturesque, and rigidly judicial. But as a clear and well-connected record of facts it is of great value, and may be safely relied upon. James Parton (born 1822) has produced several biographies of eminent citizens of the U. S. which have an historical purpose and value.

Southern America, and Spain as connected with it, have been illustrated by the labors of William Hickling Prescott (1796–1859), perhaps the most charming of all English historical writers, and inferior to none in patient research. His histories of Ferdinand and Isabella, of Philip II., and of the conquest of Mexico and the conquest of Peru, are rightly regarded as the most fascinating series of historical works in our language. Arthur Helps has written a "History of Slavery," which, animated by a thoroughly humane and loftily philanthropic spirit, presents his subject with his characteristic calmness and reserve.

The history of Greece has been written by William Mitford (1744–1827) with learning and the feeling of a true scholar for his great theme; Bishop Thirlwall (born 1797) has also produced a valuable history of the Hellenic peoples; but the work which displaces all others in English literature upon this subject is that of George Grote (1794–1871), who seems to have penetrated the very heart of Greek life, political, social, moral, and intellectual. His "History of Greece" and his "Plato" seem to present to us all that we can hope to know of the national experience and the best intellectual period of the great people who were the sources of modern civilization.

Roman history to the end of the Second Punic war has been treated by the manly pen of Thomas Arnold (1795–1842), a worthy disciple of Niebuhr, who added a certain simple English tone and charm to the manner of his master. His "Lectures on Modern History" are also admirable in the same way. Herman Merivale (born 1808) wrote a "History of Rome under the Empire" which supplements acceptably Arnold's more vigorous work. Henry Hart Milman (1791–1868), a poet, and the author of "Fazio," a powerful and successful tragedy, wrote a "History of the Jews," a "History of Greek Christianity," and a "History of Latin Christianity," which form an admirable trilogy of religious history.

Of war histories, the two most important are Sir Edward Creasy's (born 1812) "Fifteen Decisive Battles of the World," in which the author treats only of such battles as have had a manifest effect upon the course of civilization; and Alexander William Kinglake's (born 1802) "History of the Crimean War" (yet unfinished), which as to fact is a clear result of careful investigation, but which in spirit is a fierce impeachment of the emperor Louis Napoleon. Perhaps the volume of William Russell (the well-known London "Times" correspondent) upon the same subject should here be mentioned. Of the histories of the civil war in the U. S. none have much value; all having been written by partisans living too near the events which they describe.

An entirely new kind of historical writing has been produced by the speculative and investigating spirit of the age. It is the history, not of nations or of men, but of man. Pre-eminent in this department is the "History of Civilization," left unfinished by Henry Thomas Buckle (1822–62), who sought, and with an admirable if not a perfect measure of success, to discover and describe the successive evolution of the moral influences which brought about the changes in the course of the history of the modern world. Of a like kind are the "History of Rationalism" and the "History of Morals" written by William Lecky (born 1838)—works which do to a certain extent pluck out the heart of the mystery of man's moral nature and social life. And historians who deal with mere external facts now go beyond the historical period, and we have in such books as "Pre-historic Times" and "The Origin of Civilization," by Sir John Lubbock (born 1834), and "Pre-historic Man" by Daniel Wilson (born 1816), ingenious attempts, marvellously successful to a certain point, in reconstructing the physical life of man at those dimly remote periods of which there is neither record nor tradition.

Books of travel are so considerable an element of modern literature, whether regarded as a means of literary entertainment or in their more important function of diffusing a knowledge of mankind and enabling us to study it under different climes and different forms and degrees of civilization, that they cannot properly be passed over even in the briefest compendium of literary history. But so vast has been their number in these latter days that only those can be noticed here which have some peculiar literary excellence, or which mark a period, or which have exercised some notable influence upon opinion.

John Ledyard (1751–88) belongs in time to the eighteenth century, but he is noticeable as being the first of that series (almost school) of travellers who set out with a purpose of establishing, verifying, or illustrating some cosmical fact—who are discoverers, not of new countries, but of the geographical relations and topographical condition of countries already known. Ledyard was the first of those travellers who have set out with the purpose of examining the Polar regions, and he made his journeys on foot; but after he had reached Yakootsk in Siberia the jealousy of the Russian government interrupted his journey, stayed his further progress, and thrust him out of the country. He afterwards undertook to discover the source of the Niger, but died in Africa with his purpose unattained. He did discover what he wrote in a passage that will never die—that in all climes, amid the snows of Siberia or on the sands of Africa, woman is gentle, kind, compassionate, and helpful. Among the many British travellers who have described, or professed to describe, the condition and the character of the people of the U. S., Frances Trollope (1778–1863) did more than any other to form the opinion upon that subject which has prevailed in Europe until very recently. She was a keen observer, wrote in a clear and very pleasing style, and many of her most damaging assertions were literally true. But she entered the country at its then wildest and most uncultivated parts, the frontier towns of the South and West, and did not become acquainted with the society which two centuries had developed in America until she was about leaving the country; and of this she said little. She thus produced at once a very amusing book and a very erroneous impression, which the passage of a century will hardly obliterate. Another woman, Harriet Martineau (born 1802), of masculine traits of mind, treated the same subject in an entirely different spirit, and after careful and candid study produced in her "Society in America" a somewhat successful attempt at a calm and philosophical appreciation of the American people and American political institutions. It will always be valuable as a record and an analysis of the facts and the spirit of American life at the time when it was written.

Of Eastern travellers the most conspicuous are Eliot Bartholomew George Warburton (1810–52), the author of some novels, whose studies of Oriental life were embodied in "The Crescent and the Cross;" Austin Henry Layard (born 1817), whose series of works giving the results of his excavations and investigations of the ruins of Nineveh are the most valuable contribution to the antiquarian and art history of the East ever made by an Englishman; Alexander William Kinglake, whose "Eothen" tells with such a wonderfully picturesque power the impressions which Oriental landscape, life, and manners make upon a civilized Christian from the West, and which has justly been called the most charming book of travel ever written.

Africa and its geographical mysteries, particularly that of the source of the Nile, has given to Ledyard not a few followers. Of these the most important are David Livingstone (1817–74), who penetrated to the heart of the country, crossing it twice at about 10° S. lat., traversing vast regions before wholly unknown to civilized man, and making geographical discoveries of very great importance;

and Sir Samuel White Baker (born 1821), who followed the wonderful river up to a great lake which is one of its two principal reservoirs, and which he named the Albert N'yanza. The records of their toils, exposures, perils, observations, and discoveries by these two distinguished explorers have an interest which reaches the degree of fascination, and takes them to a certain extent out of the region of geographical science into that of general literature.

Their rival in the interest of his contribution to the literature of exploration, if not in the value of his discoveries, was Elisha Kent Kane (1820–57), eminent among those for whom the North Pole and a possible north-west passage from the Atlantic to the Pacific has had an irresistible attraction. His narrative of his experience in this region of icy blankness has the interest of romance with the stamp of literal truth, not surpassed even by the fiction of Defoe's "Robinson Crusoe."

Conspicuous among American explorers, both in regard to antiquities and geography, is Ephraim G. Squier (born 1821), whose works upon the mounds of the Mississippi Valley and upon Nicaragua, Honduras, and contiguous regions of Central America are recognized as having a great and permanent value. John L. Stephens (born 1805) has also in his "Travels in Yucatan and Chiapas" revealed to the modern world a mass of interesting fact concerning the relics of the extinct races of Central America.

Frederick Law Olmstead (born 1822), first known by his "Walks and Talks of an American Farmer," afterwards wrote "A Journey in the Seaboard Slave States," "A Journey through Texas," and "A Journey in the Back Country," which are historically perhaps the most important books of travel that have been published in regard to this century, giving as they do, with all the candor and charity consistent with a love of freedom, an exact description of the social, moral, intellectual, and physical condition of the Southern States of the American Union a few years before the war of secession. Bayard Taylor (born 1825) has visited no previously unknown, or even very remote regions, but the extent of his travels, his careful observation, sound judgment, good-nature, and agreeable style have gained his works in this department of literature a wide popularity.

Philosophy.—The philosophical writers of the English-speaking peoples during the present century have shown the influence of German or of Scotch thought, or have been chiefly critical of other writers or of earlier schools. Thomas Reid (1710–96), although belonging in time to the last century, belongs by affinity to the Scotch metaphysical school of the present, which he may be said to have founded by his "Inquiry into the Human Mind on the Principles of Common Sense" and his "Essays on the Intellectual Powers," "Essays on the Active Powers," etc. He opposed the theory of Locke, and found in the innate and instinctive powers and consciousness of the mind the prime source of its knowledge and its stimulus to action. The objections against this theory were answered with great ability by Dugald Stewart (1753–1828), the next in order of the Scotch metaphysicians, whose "Elements of the Philosophy of the Human Mind" and "Dissertation on the Progress of Metaphysical and Ethical Philosophy," the former by its acute analysis, the latter by its wide-reaching knowledge and attractive style, take a high place in philosophical writing of the second or non-originative class. Among works of this class Sir James Mackintosh's "View of the Progress of Ethical Philosophy" should be mentioned. Chief of this school, and perhaps ablest of modern metaphysicians, is Sir William Hamilton (1788–1856), whose writings upon the philosophy of perception, on eclecticism, and on logic are the fruit of a profundity and grasp of his deep and subtle subjects which, whatever may be thought of their absolute soundness, even their opponents regard as efforts in the very highest style of metaphysical dissertation. William Whewell (1795–1866) took an enviable position in this department of literature by his work on the inductive sciences. And here should be mentioned Richard Whately, archbishop of Dublin (1787–1863), whose treatises on logic, on rhetoric, essays on some of the difficulties in the writings of Saint Paul, and whose anti-Tractarian "Cautions for the Times," and indeed all his writings, even those of a specially ecclesiastical character, are philosophical in tone and style, and almost so in purpose, and whose wide range of knowledge and vigorous intellect made a strong impression upon the general thought of his day. John Stuart Mill (1806–73), by his "Examination of Sir William Hamilton's Philosophy," his "System of Logic," and his "Dissertations and Discussions," etc., takes a high place among modern philosophers of the Positive school, although he cannot be regarded as a disciple or an apostle of Positivism according to Comte. His philosophical principles have been ably criticised by Dr. James McCosh (born 1811), who by a series of works, all opposed directly or indirectly to the positive and material tendencies of the day, has taken a prominent position on the conservative and religious side of philosophy. Of the same school was Dr. Francis Wayland (1796–1865), who by his "Elements of Moral Science," "Elements of Political Economy," "Intellectual Philosophy," and treatise on the "Limitations of Human Responsibility," gave to the American—or, we should rather say, the New England—branch of the literature of morals and philosophy an admitted claim to the highest respect and consideration. George Henry Lewes (born 1817) should be mentioned as a contributor to philosophical literature by his "Biographical History of Philosophy," "Aristotle," and "History of Philosophy from Thales to Comte"—works of a philosophical interest and value not always merely historical. Nor should Henry James (born 1811), a subtle and aggressively independent thinker upon the philosophy of religion, and the master of a singularly impressive and suggestive style, be passed over; nor Dr. Mark Hopkins (born 1802), in virtue of his "Lectures on Moral Science" and "Love as Law and the Law of Love;" nor George Ripley (born 1802), the author of "Discourses on the Philosophy of Religion" and "Letters on the Latest Form of Infidelity."

Theology.—As every clergyman is supposed to be more or less a man of education and of intellectual ability, and as every settled minister of a parish or congregation is required to prepare at least one sermon in every week, the amount of writing more or less theological in the English language is beyond computation, and increases weekly. Of this a quantity unaccountably large is printed. We can, however, notice here only a very few even of the more distinguished clergymen who have made themselves known in literature in the present century. Robert Hall (1764–1831), a Baptist minister who for eloquence has been compared to Burke, and for fanciful richness of illustration to Jeremy Taylor, is distinguished not only by his sermons, but by his "Christianity Consistent with the Love of Freedom," his "Apology for the Freedom of the Press," and his "Modern Infidelity." John Forster (1770–1843), also a Baptist minister, was not remarkable for pulpit eloquence, but his essays, particularly those on "Decision of Character" and the "Evils of Popular Ignorance," are among the most thoughtful and weighty productions of their class in English literature. Thomas Chalmers (1780–1847) has probably been unapproached in eloquence and the vigor of his personality by any clergyman of the century. He was the most fervid and earnest of pulpit orators. His "Institutes of Theology," "Commercial Discourses," "Evidences of Christianity," and "Astronomical Discourses" are his principal works. Isaac Taylor (1789–1865), a religious essayist of distinguished learning and ability, has discussed in "Ancient Christianity" the doctrine and the discipline of the early Christians, directing himself to the teachings of "Tracts for the Times," a very remarkable and influential series of religious publications with a strong leaning toward Romanism, of which the principal writers were Edward Bouverie Pusey (born 1800), John Henry Newman (born 1801), John Keble (1792–1866), and Richard H. Froude (1803–36), all clergymen of the Church of England and of the extreme High Church school, and all writers of independent theological works which have had a strong but, it begins to appear, not an enduring effect upon the tone of religious thought among the members of that Church. Frederick W. Robertson (1816–53), a preacher whose sermons produced more effect upon the lives of men than those of any other modern minister of which there is literary record, stood at the very ecclesiastical antipode of the Tractarian men. His style was fervent, strong, and direct, his thought independent; he labored for the bettering of the working-classes, and he was suspected of rationalism in religion and socialism in politics. Doubts which must have occurred to many thoughtful readers as to the literal truth of many passages in the historical parts of the Old Testament, particularly in the earlier books, found strange and unreserved expression in a series of volumes by an eminent mathematician and clergyman of the Church of England, John William Colenso (born 1814), bishop of Natal, the first of which was "The Pentateuch and the Book of Joshua Critically Examined." Bishop Colenso had previously written several mathematical works, and he brought to his task habits of close reasoning and a calculating spirit, which led him to test these books by a standard to which Oriental writers, profane or sacred, never thought of conforming. Coming from such a quarter, his books, which he did not regard as at all impairing the divine origin of the Christian religion, produced a profound impression and very serious disturbance in the English Church, by the Convocation of which they were condemned. Theodore Parker (1810–60), at first a Unitarian minister,

was a doubter of a very different character. His faith was in God and in man, but not at all in revealed religion. A man of wide and varied learning, of independent spirit, of a tender and loving nature, the champion of the oppressed, the benefactor of the poor, his preaching the earnest utterance of his own strong personal convictions, he did much to unsettle the belief and to confirm the disbelief of a very large number of the most intelligent and purest minds in New England. Octavius B. Frothingham (born 1822), the ablest of his disciples, has hitherto published little except from the pulpit; but his ability, his earnestness, and the polish of his style, in which he is superior to his master, make him the leader of rationalistic religion in America. Henry Ward Beecher (born 1813), the ablest member of an intellectually gifted family, and a Congregational minister of the broadest and most liberal theological views, is regarded as the greatest pulpit-orator in America—an eminence which the style of his published sermons perhaps hardly warrants. But the stenographer can report the orator's words, but not the orator. Mr. Beecher is the leader of the most independent and liberal school of Christians in the U. S. His writings are voluminous and various. Among them are "Lectures to Young Men," "Star Papers," a series of miscellaneous essays, and "Norwood," a novel.

Political and Social Science, properly speaking, are the product of the present century. Among the English works in this field the most important are those of Jeremy Bentham (1749–1832), to whom, next to Adam Smith, belongs the honor of originating the science of political economy. The mere titles of the various works produced by him in his laborious and self-sacrificing life would fill half this page. The spirit of all of them is concentrated in his famous saying, "The greatest good of the greatest number"—*good* here meaning material comfort and the happiness consequent thereupon. David Ricardo (1772–1823) published works of authority on the principles of political economy, giving his attention chiefly to the subjects of labor and currency. Thomas Robert Malthus (1766–1834), also a political economist, in his "Essay on the Principles of Population as it Affects the Future Welfare of Society" showed that population always rises to the level of possible subsistence. This work, in the words of Brougham, "divides (with Ricardo) claims to a second place after the 'Wealth of Nations.'" The greatest of Bentham's disciples, John Stuart Mill (1806–73), by his "Essays on Unsettled Questions in Political Economy," his "Principles of Political Economy," his essay on "Liberty," his "Considerations on Representative Government," and his "Subjection of Women," has wrought into a systematic working form the principles of the Benthamite school, of which he was, and will probably long be, regarded as the chief apostle. His works are masterpieces of far-reaching thought and subtle reasoning. Of less note, but of high and well-deserved reputation, are the works of Henry Fawcett (born 1833). Francis Lieber (1800–73), born and educated in Germany, but for the greater part of his mature life a citizen of the U. S., is the author of several profound works in this department of literature, of which the most celebrated are his "Manual of Political Ethics," "Legal and Political Hermeneutics," "Essays on Property and Labor," and "Civil Liberty and Self-Government."

The champion of the "protective" system of political economy as opposed to free trade and all unrestrained commercial intercourse, particularly in articles which are or may be of domestic manufacture, is Henry C. Carey (born 1793), whose "Principles of Political Economy" and various other works embody in stringent phraseology all that can be said on this side of the question. Most of Mr. Carey's works have been translated into nearly all the languages of Europe. Herbert Spencer is the most eminent of recent writers in this department. His works cover the ground of psychology, biology, what he calls "sociology"—*i. e.* the philosophy of society—and morality, which it would be difficult to separate from the latter. In a word, he has attempted to work out a complete system of practical philosophy. His views on education are original and far-reaching. Indeed, he is one of the clearest and coolest thinkers of the age.

Of British writers upon education, one of the most important subdivisions of this department of literature, and which has recently received attention commensurate with its importance, the Rev. Henry Parr Hamilton (born 1794), the variously learned Francis William Newman (born 1805), and the distinguished physiologist Huxley (mentioned again below), must be mentioned. In America two of the most distinguished are Henry Barnard and Frederick A. P. Barnard. The latter's "Letters on College Government" is regarded as "the ablest treatise on the higher education yet published in the U. S." He is also the historian of the U. S. Coast Survey and the author of an "Analytical Grammar." Besides these, Horace Mann, Francis Wayland, A. D. Bache, and W. T. Harris have written upon this subject with marked and widely recognized ability.

Jurisprudence is hardly a part of literature in the common acceptation of that term, even although we do not regard it as the equivalent of the somewhat old fashioned phrase *belles-lettres*. But the "Commentaries" of Sir William Blackstone (1723–80) upon the laws of England added a lustre and a charm to their dry and technical subject, and perhaps even deserved the conventional term "elegant" which was applied to them. They have certainly much of the interest of history. Appearing soon after the middle of the eighteenth century, they occupied this field with such a weight of authority that there seemed nothing to be done but to accept them and to comment upon them. For we pass over, of course, mere reports and technical treatises, like, for instance, Fearne on "Contingent Remainders" or Chitty on "Pleading," which have no more literary interest or character than demonstrations of mathematical problems or than tables of logarithms. In this department mere mention must be made of Delolme's (1745–1807) work on the British constitution; "The Federalist," a collection of papers by Alexander Hamilton, James Madison, and John Jay, which had a very important influence in bringing about the adoption of the Federal Constitution of the U. S.; Edward Livingston's (1764–1836) "Plan of the Penal Code of Louisiana" and "System of Penal Law" for that State; John Marshall (1755–1835), whose judicial decisions, according to an eminent British critic, "would have done honor to Westminster Hall in the proud season of British law;" James Kent's (1763–1847) "Commentaries on American Law," which for their style, as well as for their matter, are in Europe, as in America, successful rivals of Blackstone's; Joseph Story's (1779–1845) "Commentary on the Constitution of the United States;" Henry Wheaton's (1785–1848) "Elements of International Law," which has become authoritative; Lord John Campbell's (1779–1861) "Lives of the Lord Chancellors" and "Lives of the Chief-Justices of England;" Theodore Dwight Woolsey's (born 1801) "Introduction to the Study of International Law," which has given him, distinguished as a classical scholar, an authoritative position universally recognized upon its subject; George Ticknor Curtis's (born 1812) "Comments on the Jurisprudence of . . . the Courts of the United States" and "History of the Constitution of the United States;" Walter Bagehot's work on the "English Constitution;" Sir Henry J. S. Maine's (born 1822) "Ancient Law" and "Village Communities;" and perhaps Sir Arthur Helps' wise treatise on "Government" should be added. This list is incomplete, but it is believed to include the principal works of this class which have been produced in this century, and which can be regarded as within the pale of literature.

Here, between our record of the literature of political and social science, of jurisprudence, and of natural science, is the fittest place to mention Henry, Lord Brougham (1779–1868), who wrote upon all these subjects, and who never wrote or spoke without impressing readers or hearers with the weight of his thought and the intelligent earnestness of his manner. The extent of his acquirements caused him to be called "a man of vast and various misinformation," and on his being made lord chancellor subjected him to the remark by Sugden, that "if the new lord chancellor only knew a little law, he would know a little of everything." But these were the jeers of specialists envious that the man who was great in their department of intellectual effort could also attain distinction in others; a not uncommon manifestation of human weakness. By his varied and voluminous writings Lord Brougham produced a marked and an enduring effect upon his time; and his efforts were always for the diffusion of knowledge, and toward liberty of thought and of action, subject to good morals and well-established law.

Natural Science, like jurisprudence, is hardly literature (whence the distinction so constantly drawn, "science *and* literature"), but it would be difficult to deny a very high literary quality to the works of many of the naturalists who have given to the present century that scientific eminence which is its peculiar glory. Of these the most eminent are Joseph Priestley (1733–1804), who, living into the present century, labored chiefly in the last, a distinguished leader in the modern school of natural science. He wrote upon government, history, and even upon grammar; but the works by which he impressed the world were those in which he brought natural science to the support of materialism; Joseph Black (1728–99), whose discoveries of the properties of fluids and of latent heat led to great results, and whose lectures became celebrated throughout the world; Thomas Young (1773–1829), the reviver and

demonstrator of the truth of the undulatory theory of light, who first deciphered hieroglyphics by the aid of the inscriptions on the Rosetta Stone, whose "Lectures on Natural Philosophy" are even at this day a treasure-house of scientific truth to the investigator, and whom Tyndall has pronounced to be the greatest intellectual power in England since Newton's day; Sir Humphry Davy (1778–1829), the discoverer of the qualities of nitrous oxide and of the metals of the alkalies, the inventor of the miner's safety-lamp, and whose scientific sagacity was adorned with a charming style which makes his "Salmonia" and "Consolations in Travel" classic books; Sir David Brewster (1781–1868), whose works cover an extended field of science, including biographical appreciations of great natural philosophers, but whose most interesting philosophical writings are those which record his investigations and develop his theories upon light; Sir John Frederic William Herschel (1792–1871), the eminent son of an eminent father, whose principal works are his "Treatise on Physical Astronomy" and "Results of Astronomical Observations at the Cape of Good Hope," which map out the whole starry heavens; Sir Charles Lyell (born 1797), first of English geologists, by whom attention was drawn to the ancient changes in the earth and its inhabitants as illustrated by its geological monuments, and whose books of travel in the U. S. are among the few of much value; William Buckland (1784–1856), who brought a profound acquaintance with geology and mineralogy to the support of religion; Sir Charles Bell (1778–1842), who made surgery one of the fine arts, and by his work on "The Hand, its Mechanism and Vital Endowments," revealed marvels and mysteries of design where the unlearned reader would least expect them; Sir Roderick Impey Murchison (1792–1871), who attained the highest geological distinction by the conception and establishment of his Silurian system, by which he brought under scientific light a formation of rock beneath the old red sandstone; this, named Silurian from the place in England where he studied it, he followed into Norway and Sweden, and finally into Russia, his book recording his geological survey of which vast country is one of the most important works of modern science; Michael Faraday (1794–1867), the most eminent of English experimental chemists; Mary Somerville (1780–187–), one of the very few real women of science the world has seen (the womanhood being as true as the science), whose works on the "Mechanism of the Heavens" and the "Connection of the Physical Sciences" have won the highest approval both for their profundity and their clear and simple style; and Hugh Miller (1802–56), a quarryman who from observations made during his daily labor became one of the leading geologists of his day, adding to exact knowledge a beauty of style and a richness of illustration rarely found in scientific books. He took his place among those men of science who seek to support revealed religion and to reconcile the Mosaic cosmogony with the records of nature. His principal works are "The Old Red Sandstone" and "The Testimony of the Rocks." In 1845 appeared an anonymous volume, "Vestiges of the Natural History of Creation," a work which, at first spoken of slightingly by scientific men as the fruit of presuming sciolism, proved to be the first utterance of the new school of development. Its style, no less than its startling views, won it worldwide attention, but as to its authorship, it still remains the "Junius" of scientific literature. Charles R. Darwin (born 1809, grandson of Erasmus Darwin, 1731–1802, author of the "Botanic Garden" and "Zoonomia") is the leader of the school of development. He had published several works on natural science, the high value of which was recognized, when his "Origin of Species by means of Natural Selection" renewed the surprise which followed the publication of the "Vestiges of Creation;" and yet, although it prepared the way for, and led naturally to, his last work, "The Descent of Man and Selection in Relation to Sex," that book was received with a mingling of admiration and horror for the author who seemed to prove that "man is descended from a hairy quadruped furnished with a tail and pointed ears, and probably arboreal in its habits." Louis John Rodolph Agassiz (1807–74) is eminent among the natural philosophers of the century by his works upon fishes, living and fossil, but chiefly by his glacial theory of certain geological formations, which he developed in his "Studies of Glaciers." In comparative zoology and comparative physiology his investigations have been of great importance and interest. He did not accept the theory of development. John Tyndall (born in 1823) is also distinguished for his glacial researches, his analysis of the solar ray, his discoveries as to light and heat, and is one of the school of philosophers to which Darwin and Huxley and the author of the "Vestiges" belong. His writings and his lectures have an intrinsic charm besides their scientific value. Thomas Henry Huxley (born 1825) is distinguished as the author of "Man's Place in Nature," "Lectures on Comparative Anatomy," "Lessons in Elementary Physiology," and other works, all of a "positive" or quasi "positive" character and materialistic tendency. Of American scientific writers, some of the most distinguished are Alexander Dallas Bache (1806–67), whose place in education has already been mentioned, but who was eminent in magnetic and meteorological science, whose many contributions to the proceedings of the American Association for the Advancement of Science are among the most valuable in the repertory of that society, and whose work as superintendent of the U. S. Coast Survey makes the shore of our northern continent his monument; Samuel George Morton (1799–1851), naturalist and ethnologist, author of "Crania Americana" and "Crania Egyptiaca;" George R. Gliddon (1807–57) and J. C. Nott, whose "Types of Mankind" and "Indigenous Races of the Earth," although criticised severely by men of science and theologians, are filled with effective groupings of significant facts illustrated by ingenious suggestions; Asa Gray (born 1810), one of the most eminent botanists of the day, as he has shown in his various works upon the *flora* of North America; Benjamin Silliman (1776–1864), the geologist and mineralogist; John Torrey (born 1798), botanist, chemist, and metallurgist; and Arnold Henry Guyot (born 1807), who brought to his adopted country a profound acquaintance with physical geography, previously set forth to the scientific world in works of recognized value, and now diffused among younger students by his books of elementary instruction. Among naturalists, John James Audubon (1780–1851) must not be forgotten, because of his close observation of the habits of birds and his great series of life-size paintings of the birds of America. Henry Maudsley's writings upon what may be called mental physiology are of the profoundest scientific and psychological interest, and have a singular literary charm. His "Body and Mind" and "Psychological Essays"—in the latter of which is a subtle appreciation of the character of Hamlet—and his "Physiology and Pathology of Mind," are his principal works. The latter of these works, rich with the lore of various ages and climes, not only interpreting what we are not sure that the greatest intellect the world has produced meant to be interpretable, but seeking to penetrate to the very seat and reveal the very mode of thought, was published in 1873. To such a point has the English language and literature advanced from the rude condition and remote period at which we first considered it. RICHARD GRANT WHITE.

English Mills, a post-village of Lycoming co., Pa.

English Pale, called also the **Irish Pale,** or simply **The Pale,** denotes in history that part of Ireland which was under English law previously to the final and complete subjugation of Ireland. In a general way, the English Pale may be defined as corresponding with the present province of Leinster, besides Cork, Kerry, Waterford, Tipperary, and Limerick. But, in point of fact, the actual Pale was much smaller than this, and, though of extremely variable limits, scarcely ever reached the dimensions indicated above. The counties of Dublin, Meath, Carlow, Kilkenny, and Louth were almost always within the Pale; Wexford and Waterford, though hardly within the Pale, were firmly English; while Wicklow and Kildare, though nominally within the Pale, were Celtic, and to a considerable extent independent. In strict language *the Pale* denotes the "boundary-line," but it is commonly used for the whole region indicated above.

English Prairie, a post-village of McHenry co., Ill., in Burton township, 6 miles E. of Richmond, 2 miles S. of the Wisconsin line, and 50 miles N. W. of Chicago.

English River, an estuary of South-eastern Africa, communicates with Delagoa Bay about lat. 25° 58′ S. and lon. 32° 36′ E. It receives several broad but unimportant streams (Tembia, Mattol, and Dundas rivers), and is surrounded with mangrove flats.

English River, in Iowa, is a branch of the Iowa River. It rises by two forks, the North and South, which unite and flow eastward, entering the Iowa River 15 miles S. of Iowa City.—Another English River enters the Red Cedar River in Black Hawk co., Ia.

English River, a township of Keokuk co., Ia. P. 1221.

English River, a township of Washington co., Ia. Pop. 1501.

English Roscius, The, a title often bestowed upon David Garrick (1716–79), the eminent actor. The title of "the Young Roscius" in like manner was given to W. H. W. Betty (1791–1874), an English actor who acquired when a child great fame and fortune upon the stage, though his appearances as an actor in adult life were failures. So also Samuel Foote (1722–77) was called the "English Aristophanes;" John Oldham (1653–83) the "English Juve-

nal;" Dean Swift (1667–1745) the "English Rabelais." Mary D. Robinson (1758–1800), a beauty, wit, and Della-Cruscan poetess, was called the "English Sappho." She was a mistress of George IV. Richard Cumberland (1732–1811) was called the "English Terence," and the kings Henry VII. and James I. were each called the "English Solomon."

Eng'lish's Creek, a post-village of Egg Harbor township, Atlantic co., N. J., on a creek of the same name, 15 miles S. W. of Absecom.

English Settlement, a post-village of Clay township, Marion co., Ia., 8 miles S. W. of Pella.

English Seventh-Day Baptists. See SEVENTH-DAY BAPTISTS.

Eng'lishtown, a post-village of Manalapan township, Monmouth co., N. J., on the Freehold and Jamesburg Agricultural R. R., 5 miles W. N. W. of Freehold.

Eng'lishville, a post-village of Kent co., Mich., 6 miles E. of Belmont. It is on the Grand Rapids Newaygo and Lake Shore R. R.

Engraft'ing, or **Grafting** [a word kindred to the Gr. γράφω, to "write;" γράφιον, a "pencil," referring to the pencil-shape of the scion or graft], the uniting of a shoot (the scion or graft) of one variety of plant (mostly of fruit trees) upon the stock of another variety, or even another species, so that the scion shall live and grow as if a part of the tree upon which it is grafted. Many reports have been published of trees grafted upon species of widely different genera and orders of plants, but it is believed that such reports are not founded in truth. Whether grafting could be practised upon animals has been disputed; but skin-grafting (the transplanting of a small piece of skin to denuded portions of the human body, there to grow and cover the whole naked patch) is an established operation in surgery; and many reports of the successful grafting of spurs, feathers, combs of cocks, etc. have of late frequently been published, mostly from French sources. These experiments are somewhat damaging to our ideas of personal identity, but there seems to be no reason why engrafting should not succeed upon animals as well as upon plants.

In selecting stocks for grafting, care should be taken not to insert a free-growing variety upon one which is slow of growth, lest an unsightly over-development take place above the point of union. In some cases, however, as when dwarfs are desired, the stock to be grafted upon is to be of much smaller growth. Thus, the pear is dwarfed when set on the quince; the cherry on the mahaleb; the apple on the thorn. There are many styles of grafting, but in all the principle is to place the alburnum or sapwood and the cambium (or new wood) of the scion against that of the stock. The hard wood of scion and stock never unites. There is no question but that some stocks decidedly affect, for better or for worse, the quality of the fruit grown upon the graft, but in most cases the effect is not strongly marked.

Among the more important kinds of engrafting we may mention: (1) *cleft-grafting*, very commonly employed where the stock is much larger than the scion. Here the stock is sawn across, its end split once or more, and one, two, or more scions, the lower end flattened into a wedge, are inserted in the cleft. (2) *Crown-grafting* is cleft-grafting when more than one cleft is made; or in other cases it is the insertion of a scion, the lower end of which is cut very thin, into a space between the wood and bark of a large stock, which is cut off, as in cleft-grafting. This method is highly approved. (3) *Splice* or *whip grafting* is done with a stock of the same size as the scion. They are simply spliced together, tied and waxed, as hereafter shown. (4) *Saddle-grafting* is accomplished by shaping the upper end of the stock into a wedge and cutting a corresponding notch in the scion. (5) *Tongue-grafting* is the reverse of this, the scion forming the wedge. (6) *Peg-grafting*, rarely used, is like tongue-grafting, except that a hole is bored in the end of the stock, and the scion, neatly sharpened into a peg, is fitted exactly to the stock. (7) *Shoulder-grafting* is done by cutting shoulders in both stock and scion, which are otherwise fitted as in splice-grafting. (8) *Budding* is a kind of grafting in which the bud of one kind of tree is inserted under the bark of another. (9) *Flute-grafting* differs from budding in that a ring of bark is taken off with the bud and inserted upon the stock in the place of a piece of bark of corresponding size which has been taken off. (10) *Inarching*, or *arcuation*, takes place when the scion is not detached from the parent stem until after union has taken place between stock and scion. (11) *Side-grafting* is the insertion of a scion into the side of the stock without cutting the stock off.

In all varieties of grafting, except cleft and crown-grafting, it is necessary to tie the scion to its place. Strips of bass matting or of waxed muslin are generally used. In all cases it is necessary to exclude the air from the cut, either by means of grafting-wax (a mixture of resin and beeswax, softened with tallow) or of clay mixed with horse-dung, a compound now seldom employed.

Grafting succeeds best when the scions have been kept for some time and become partly dried. The scion should be cut before the buds begin to swell. Grafting is done in the spring, but budding may be performed in autumn also.

Engrailed, in heraldry, a line or other object edged with small semicircles or crescents, the points of which are turned outward, is said to be *engrailed*. The semicircular marks or dots around the edge of a coin are called engrailments. The term doubtless comes from the French *grêle*, "hail."

Engra'tia, SAINT, lived at Saragossa in Spain in 304. She was persecuted as a Christian under the emperors Diocletian and Maximianus Herculeus; and, according to the poet Prudentius, she underwent the most fearful tortures, but notwithstanding the dreadful mutilations which she received, she survived to a great age, and died in the odor of sanctity. Her relics are preserved at Saragossa. She is honored by the Roman Catholic Church on April 16.

Engraving. Engraving on precious stones, glass, or metals, in such a manner as to represent the figures or objects in relief, is a very ancient art, and, strictly speaking, a branch of sculpture.

We shall in this article confine ourselves wholly to the engraving, on metal or wood, of figures or designs, in such a way that when charged with any coloring-matter and pressed upon paper or parchment, an exact representation, in outline and shadow, of the engraved figures or designs will be produced. The impressions thus made are called engravings. This term is also applied in popular language to stone-printing or lithography, but as ordinarily there are no incisions made upon the face of the stone, and the processes differ widely from engraving proper, we prefer to treat of this branch of art under its appropriate title.

Engraving, in this restricted sense, is a modern invention, and grew into use and importance with the art of printing, of which, in fact, it forms a constituent part. Whether we consider the difficulty attending its execution, its value in multiplying the essentials of other departments of art, its use in illustrating science and industrial processes, engraving takes an elevated position, both from an æsthetic and a practical point of view.

In giving some account of the technical processes of various kinds of engraving we shall not hold in mind the necessities of the professional engraver seeking aid for perfecting himself in the art, but rather those of the general reader or connoisseur, who seeks the elementary knowledge requisite for an intelligent estimate of the best products of the engraver's skill. It has been well said by Adam Bartsch that it is impossible to convey in writing any but the most general instructions regarding the technical processes of the art. We shall, therefore, in the outline which we propose to give, exclude all details of handling not pertinent to the end we have in view.*

1. *Wood Engraving.*—This is the most ancient branch of the art, and for the purposes of illustration has been held to be of the greatest value from the time of its introduction. Boxwood is most generally used by engravers, although any hard and close-grained wood may be made available. It is first sawed across the fibre, in thickness equal to the length of ordinary metal types. The surface of the wood is then made smooth and covered with flake-white. Upon this is drawn in fine lines with pen or lead-pencil the design required. In many instances now the expense of drawing is entirely superseded by photographing, directly upon the block, the subject to be engraved; and there is still another process in use whereby the subject is copied by transferring an impression with ink upon the block, which also avoids the expense of drawing and greatly facilitates the work of the engraver. The white or untouched parts between the lines of the drawing are then cut out by means of variously formed chisels and gouges. This process leaves the outlines and shadows elevated, like the faces of type in a printer's form. When the blocks are inked by an ordinary roller, impressions may be taken off upon paper by means of a press. In point of fact, however, the wooden blocks are now scarcely ever used for printing. When the engraver's work upon the wood has been completed, a

* *Publishers' Note.*—For a more practical view of some of the details of engraving, see the article ENGRAVING STEEL AND COPPER PLATES, ETC., written by a practical steel engraver of New York City. Though the two articles to some extent cover the same ground, their great excellence will, it is believed, warrant the publication of both.

mould of wax is taken from the block, and within this mould a thin plate of copper is deposited by electro-galvanic action. Upon the back of this copper a casting of type-metal is fixed, which by means of tin-foil is amalgamated with the copper, forming a solid plate of sufficient strength to be securely fastened upon a wooden block of the proper thickness for the printer's form. By this means also, a much larger number of clear impressions can be secured than from the block itself. In wood engraving effects are generally produced by parallel lines. In finer work, however, cross-hatching (or the use of lines transversely intersecting each other) is introduced, by which artists approach the delicate transitions and effects of line engraving on steel or copper.

2. *Etching.*—For this process a plate of metal, generally copper, is prepared with a perfectly even and smooth surface. It is then thinly covered with a varnish composed of various proportions of white wax, black and white pitch, and asphaltum. This varnish, technically called the "ground," is spread in a thin coating over the prepared plate, and afterwards smoked to give a black surface, the better to show the drawing of the artist's design. The drawing is made in reverse upon the varnished plate, generally by transfer of a drawing made upon paper with colored chalk. When the outlines are clearly marked upon the blackened surface, they are cut through the varnish by the etching-needle, laying bare the surface of the copper or metal used. The etching-needle is a steel instrument similar to a sharpened lead-pencil, and points of different degrees of fineness are used as a finer or heavier line is desired. When the outlines and shadows of the object to be etched are thus cut through the "ground," a rim, or dike, of wax is made around the border of the plate, and some corroding mixture (generally nitric acid mixed with an equal quantity of water) is poured upon the plate. By the action of the acid the lines laid bare with the etching-needle are bitten into the plate, each with a breadth corresponding to the surface laid bare by the needle. If it is desired that the lines shall be of unequal depth, the acid is poured off, and the lines whose depth is deemed sufficient are in technical language "stopped out" by being washed with water, dried, and covered with varnish, while upon the remaining parts the process of corrosion is continued till the unprotected lines are as deep as the etcher may desire. The ground or varnish is then removed from the plate, the oxidized portions are cleansed, and a proof is taken. If the work is in any part unsuccessful, it may be touched up and rendered more expressive by the "dry-point." This is a fine and sharply pointed steel instrument, by which scratches or shallow grooves of great delicacy are made on the smooth portion of the plate. Some etchers use the dry-point very little, if at all. Others rely upon it for their finest effects.

3. *Line Engraving.*—This is the most elaborate and costly process for the reproduction of works of art. The metal plates, whether of copper or softened steel, are prepared as for etching, but with a more careful polish. The work of art to be engraved is drawn from the original in the reduced size required for the engraving. The plate is generally covered with a thin coating of wax. The pencil drawing is then laid with its face upon the wax, and gently rubbed by a burnisher. This, as in the preparation for etching, transfers the outline to the wax. The design is then traced through the wax upon the metal with an etching-needle. The wax, when melted off, leaves the outline marked on the plate, ready for the burin. The burin or graver is a square, or lozenge-shaped, piece of steel inserted in a pear-shaped handle, the instrument itself being sufficiently thick not to bend under strong pressure of the hand. The end is diagonally ground, so that one side of the instrument presents an acute angle, which, when pushed forward by the hand, cuts out triangular grooves in the metal. The burnisher, above alluded to, is a piece of hardened steel, smooth and rounded for the purpose of toning down work too deeply cut, or for polishing the plate in case of accident to the surface. The "scraper," also used, is a triangular piece of steel, otherwise shaped like a knife, with its angles brought to a sharp edge, and inserted in a handle. This is used to scrape off the furrow of metal which is raised on the plate by the action of the graver. This raised furrow is called the "burr." Thus equipped, the engraver cuts grooves into the plate which, when filled with ink, come to represent by their curves, crossings, and varying depth and breadth all the outlines, shadows, and transitions of the picture from which he works. Of the combination of other modes of engraving with lines we shall speak hereafter.

4. *Mezzotint.*—This process was invented at a later period than either of those which we have described. It has been attributed to Prince Rupert by some, but on the authority of Heinecken to a German military officer named Von Siegen. The plate should be prepared as for the graver. By the means of a rocker used by the hand, or a machine covered with fine teeth, the whole surface of the plate is covered with a compact series of minute incisions—so compact that if filled with ink the plate would give a printed surface on paper quite black. Upon this surface, thus covered with "burr," the outlines of the picture are drawn, and where lights are desired the burr is removed by the scraper and made smooth by the burnisher. The transitions from the high lights to the deep shadows are delicately marked by the continuously increasing amount of the "burr" which is left on the plate.

5. *Stippling.*—This consists in puncturing the metal plate by dots made with the point of the graver or by corrosion with acid. Sometimes these dots are made by slight blows upon the graver. The greater or less number of these dots gives in printing all varieties of shading. This was a favorite method with Bartolozzi and his school.

6. *Aquatint.*—This method of engraving, now little used, is designed to imitate drawings in India ink, bistre, or sepia, especially those which are on a large scale. The method generally followed is this: The outline of the objects is first etched in the usual manner. The plate, when cleaned, is evenly covered with finely powdered mastic. It is then warmed till the mastic particles are melted sufficiently to cause them to adhere to the plate. Between the particles of the mastic bare spots are left, upon which the acid can afterwards act. Upon those parts of the plate where shadows are not required a thick varnish is laid on with a brush, to protect it. The acid is then poured on as in etching. When the lightest shadows are sufficiently bitten by the acid, those parts are stopped out by varnish, and the work is permitted to go on until the deepest shadows are finished. For landscapes or trees, where special freedom is required, modifications of this process are made which are not sufficiently important for description.

7. *Graphotype.*—This is a modern invention, a description of which we copy from a recent writer: "Finely powdered chalk is spread thickly on a metal plate, and then subjected to hydraulic pressure till it becomes a solid mass with a beautiful white surface, slightly shining, but not inconveniently brilliant. On this surface the artist draws in a glutinous ink, perfectly black, flowing from a finely pointed little brush; the pen cannot be used, on account of the friability of the chalk. The ink glues the particles of chalk where it passes, and when the drawing is complete the white spaces between the lines are easily hollowed by rubbing them gently with a piece of velvet or a light brush. The black lines remain in relief, like the lines of a wood-cut. The plate is then dipped in a solution of flint, and so hardened, after which a stereotype cast or an electrotype copy is taken from it, and this is used as a stereotype or electrotype." The effect produced is somewhat similar to that of wood engraving.

8. *Combination of Processes.*—For the sake of clearness we have described the different modes of engraving as distinct processes, but they are quite often combined. In etching, the dry-point is constantly made use of, and not seldom the graver. In line engravings the outlines are often etched, while the most important and expressive parts are worked out with the graver. Stippling is made use of at times to give softness to the expression of the face. In etching, parts of the plate are sometimes made to give delicate shadows and transitions by the "burr" used in mezzotint. In line engraving, short lines or dots are inserted in the lozenge-shaped intervals between the cross hatchings made by the graver.

9. *Handling.*—Every engraver of note adopts some methods of producing his desired effects peculiar to himself. This is technically called "handling." Many of the elements which enter into handling are common to the painter and the engraver. Both alike must attend to drawing, anatomy, and perspective, both linear and aërial; to chiaroscuro, or the general distribution of lights and shadows in a picture, and the various gradations of depth and delicacy of the latter as they recede from the focus of light. They must both alike seek for truth and force in the representation of the outline surface and texture of bodies; they must alike take account of the variations which distance, quality of the light, and atmosphere produce in objects by their manifold changes. In addition to these, the engraver (if he does not engrave his own design) must be a translator of another's thought into a different language. This he can never accomplish without the greatest familiarity with his own language, as well as that of the painter. Literal interpretation will fail as really as in the case of translating a great poem. The chief study of the engraver is so to arrange his lines as to mark the character of each object and feature, distinguish it from every other, and give it the proper prominence and importance with regard to the total scene or event which the picture is designed to represent. The color of the picture, it is true, cannot be, strictly speak-

ing, translated, but it is possible to convey an accurate idea of the relations of the lights and shadows which the different colors embody. Painters select colors with reference to their desire to make special objects prominent, and to attract and fix upon them the eye of the spectator. Now, the engraver, if he cannot imitate the *color*, can produce by his lines such an effect as shall imitate the *emphasis* which the painter expresses by actual color. From this point of view critics speak of "color" in an engraving. The methods in which different artists express color, flesh, hair, drapery, etc. would extend this article beyond the limits we have set to ourselves. These are best studied by the learner in the works of eminent engravers through a comparison of their methods with each other.

10. *Printing.*—Much of the effect of all engravings is dependent upon printing. In wood engraving, by reason of the lines being raised in relief like types, the difficulty of printing is less than in other branches of the art. It requires, however, to make good impressions, all the accessories for the best work of the printer's art. Clearness, delicacy, and softness in wood-cuts are greatly dependent upon the skill and judgment of the printer. In those departments of the art in which the ink or coloring-matter is received into grooves or dots sunk beneath the surface, the process of printing is much slower and more difficult. The ink is forced carefully into the depressions with a soft ball or dabber, and afterwards the portions of the plate between the grooves, and also the lightly worked parts which represent the lights, are carefully cleaned with a soft cloth and the palm of the hand before it is ready for the press. This process is a slow one, and requires special training on the part of workmen. The printing of etchings is so important that many etchers provide themselves with hand-presses, and work off their own proofs. Hamerton, in his "Etching and Etchers," names specially one house in Paris and one in London which alone he speaks of as capable of good work in printing etchings. A copper plate soon wears so much as to give blurred and imperfect impressions. Two hundred impressions of an etching and five hundred of a line engraving are said to be the limit which a copper plate can furnish without an appreciable deterioration of quality. Since the art of coating the copper plates with a thin layer of steel has been introduced, a much larger number can be produced. Since the time of our countryman, Jacob Perkins, who introduced the use of steel plates, copper has been to a great extent laid aside, so far as line and mezzotint engraving is concerned. Steel has been made especially useful in engraving banknotes, in which especial complications and delicacy of lines are desirable in order to increase the difficulty of counterfeiting. Engraved steel plates, when hardened, are capable of giving to steel cylinders rolled over them, under enormous pressure, a representation in relief of the sunken lines of the plate. These cylinders, when hardened, are made to transfer the lines to other plates of softened metal, which in turn are hardened and used for printing. These plates, when worn, are retouched by reapplication of the same cylinders. In this way plates may be duplicated, or the same plate be made to give an almost unlimited number of impressions.

At an early period the practice of using two or more blocks in wood engraving was introduced. The outline was made by one block, and the different degrees of shading by others. This was called engraving in chiaroscuro. This led to printing in gradations of color by means of several blocks, each giving a single color or shade. This has been carried to a high degree of perfection. A similar process has been introduced in lithography. By this means chromo-lithographs, as they are called, have been printed which imitate the colors of small pictures with an accuracy which, though necessarily somewhat mechanical, is really surprising. In all methods which lay on colors by successively applied stones or blocks the matter of printing becomes of chief importance.

11. *Painter-Engravers.*—This is the designation given by Bartsch to those artists who have engraved their own designs, either as studies for paintings or with a purpose of giving them no further representation in color. These works are not translations or copies, as are ordinary engravings, but real autographs—direct expressions of the artist's mind. In the modern tendency to specialize and divide labor, artists have to a great extent laid aside this practice, but with the older artists it was very common. Collectors place a high value upon these autographs. They are becoming rare, and are of course much advanced in commercial value. Bartsch's great work ("Peintre-Graveur," in 21 vols.) is devoted entirely to engravings and etchings of this class.

12. *Relative Artistic Value.*—The relative importance, for art purposes, of the different modes of engraving is difficult to determine. Each has its own advantages and limitations. New processes like the graphotype have not yet been sufficiently tested to determine their permanent value. Wood engraving has a very decided advantage over the other forms of the art in respect to cheapness and facility of execution and printing. These circumstances adapt it to the purpose of illustrating books, magazines, and newspapers, and also render it liable to degradation through haste and carelessness in execution. In the hands of good artists, however, it is capable of high excellence. The best wood engraving has a softness and grace which are attractive to all. But in all the elements of truthfulness and force the distinct, sharp lines of the etching needle and dry-point are vastly superior. In etching, the artist must secure his effects by clear outlines, each of which must tell its own distinct story. The softness and amenity of wood engraving are denied to the etcher, but he may accomplish results which are vastly superior in all the higher elements of expression. For this very reason etching is never popular with persons untaught in the grammar of art. It generally fails in rendering the delicate gradations of shadow in clouds, and rarely succeeds in perfect modelling of flesh. But in "freedom, precision, and power" it is superior to all methods of engraving. For this reason, high success in etching requires special capacity, which stands somewhat apart from the art-faculty in general.

Mezzotint, like wood engraving, is popular from its softness and the perfect gradations of tint which it secures. The process is also cheaper than that of line engraving, and the facility with which it can represent strong contrasts in lights and darks and the faces of the young and fair make it a process next in popularity to wood engraving. In the hands of masters like Earlom, McArdell, and Bond it has given us works of great beauty and power. Line engraving, if not the most difficult, is the most laborious method of engraving, and for this reason, as well as for its inherent capacity for force and variety of effect, stands in the first rank among methods of engraving. It is likely, by the time which it consumes and the great manual dexterity which it requires, to become mechanical, and deficient in the breadth, freedom, and boldness of etching. But when, under the hand of a real artist, it combines these elements with perfect moulding of flesh, delicacy of tone, and gradation of shadows, it stands unrivalled among its sister branches of the art. The strength of Goltzius and Cornelius Visscher, the bold relief and brilliant contrasts of Strange and Edelinck, the aërial grace and spiritual expression of Raphael Morghen and Toschi, are sufficient to vindicate the claim of line engraving to the position which the common judgment has assigned it.

History of Engraving.—The origin of this invention is obscure. It is, however, well settled that playing cards were printed from wood blocks in the beginning of the fourteenth century, and this is ordinarily supposed to be the origin of the invention. Papillon, a French wood engraver, and author of a treatise on wood engraving in two volumes (Paris, 1766), professed, however, to have seen a volume of wood-cuts engraved at Ravenna by Alexander Alberic Cunio and his twin-sister Isabella, during the papacy of Honorius IV., A. D. 1285–87. The practice of printing cards from wood blocks continued in various parts of Europe through the fourteenth and fifteenth centuries. In the early part of the fifteenth century images of saints and other religious pictures were produced. A picture of St. Christopher, dated 1423, was until recently regarded as the earliest known wood-cut with a date, but within a few years past it has been claimed that earlier dated specimens have been discovered. At this same period, within the first half of the fifteenth century, began to appear in Holland and Germany those works now known as block-books (see TYPOGRAPHY), which were printed from engraved wood blocks. Immediately on the invention of printing with movable type, ornamental letters were cut on wood and used to beautify the printed pages. The Psalter of Gutenberg (1457) was thus ornamented. The idea seems to have been to imitate manuscript of the period, and in 1475 a Durandus was published by Zainer, at Ulm, with an ornamental vignette border to the first page, after which such borders engraved on wood were frequently used. The first book with wood-cut illustrations was a book of fables, printed at Bamberg by Pfister in 1461. Numerous books of the fifteenth century were illustrated with wood-cuts, and the art was extensively practised. We do not know the names of any wood engravers of the earliest period, but towards the close of the century we begin to meet with names. Michael Wohlgemuth is among the first, if he be not the first, wood engraver whose name can be connected with his work. To him are attributed the illustrations of the great "Chronicle" of Schedel, commonly called the "Nuremberg Chronicle," published at Nuremberg in 1493; and he is named in the work as one of the superintendents of its execution.

The early style of wood engraving was rude, but not

without artistic force. In general, however, little was attempted by the early engravers beyond outline representation. Shading and what is sometimes called "color" were unknown at the first. The earliest specimen of shading by cross lines, commonly called cross-hatching, is found in a wood-cut on the title-page of Breydenbach (Mentz, 1486).

Wohlgemuth dealt freely in heavy shading, and other work of his time shows the advance of the art in Germany. It was not, however, until the influence of Albert Dürer began to be felt that the old conventional styles were abandoned. Dürer was a pupil of Wohlgemuth. In 1498 he published his "Apocalypsis." It was the beginning of a new era in the art. Dürer applied to the work of drawing on wood, in so far as they were applicable, the same principles which governed oil painting. The result was that a wood engraving became a history or a poem. Germany at first, and afterward all Europe, felt the new inspiration. Artists appeared in all directions, and the most eminent painters did not disdain to draw on wood. During the sixteenth century a very large proportion of published books were illustrated with wood-cuts. Even statutes and books of instruction in the practice of law were illustrated. Contemporary with Dürer were such artists as Hans Burgmair, Hans Schauffelin, Urse Graff, Wechtlin, Holbein, Lucas Cranach, and many others in Germany. In regard to Hans Holbein's engravings much uncertainty exists. Some inferior work is signed with his name or initials, and pretty much all the good work of the period is attributed to him by his admirers.

Considerable discussion has been wasted on the question whether any, and if any which, of the artists actually cut wood blocks with the graver. The subject is of slight importance. They drew pictures on the wood to be engraved there, and probably directed the workmen if they did not handle the tools. They are as properly called wood engravers as Canova and Thorwaldsen are called sculptors. Lucas Cranach appears to have been the inventor of the application of wood engraving to printing in chiaroscuro, which consisted in the engraving of two or more blocks to be used in impressing different colors on the same print. An engraving of this kind by Cranach is extant, bearing date 1509. Ugo da Carpi in Italy, about 1518, adopted the suggestion of Cranach, or invented the plan anew, and the art reached great perfection in Italy, though almost abandoned in Germany.

In France the art of wood engraving was seized with alacrity in the latter part of the fifteenth century, and applied with great skill to the ornamentation of the borders of pages. The superb books of devotion which issued from the Parisian presses at this period are unrivalled elsewhere. It is impossible, however, to name with any certainty a French engraver on wood until the period of the fine issues of the presses at Lyons, after 1520, when Bernard Solomon, commonly called "Little Bernard," executed very beautiful illustrations of the Bible, Ovid, etc.

The early history of the art in Italy is also obscure. Some Italian publications of the fifteenth century seem to have been illustrated by German workmen or from their designs. Others, however, are unmistakably Italian, the vast superiority of drawing, especially of the human form, being at once visible.

At the close of the fifteenth and beginning of the sixteenth century there seems to have been in the north of Italy, possibly at Venice, an artist on wood who was employed by the book publishers in that city, in Milan, and elsewhere, and who was evidently the father of the art in Italy. Numerous cuts by him are found with the signature ℨ A, and the name Joan Andrea has been given to him. His name is, however, doubtful. The "Poliphilus" published by Aldus (1499) was doubtless illustrated by him, and is the masterpiece of wood-cut illustration in Italy for the fifteenth century.

The art flourished in Europe till the close of the sixteenth century, when its decadence was manifest, and in the seventeenth century it passed almost entirely out of use, except in rude and worthless styles, of which examples are seen in old chap-books and cheap works for the common people. Metal engraving had usurped its place in the illustration of books. The revival of the art is to be attributed to Thomas Bewick, an English wood engraver (born 1753), whose "British Birds" (1804), drawn and engraved by himself, present manifold instances of rare truthfulness and beauty. His work, at first rude, improved rapidly, and at length took high rank in the art. He was followed by his own pupils and by a succession of others, but it is only since 1830 that the art began to assume the high character which it now possesses. At present few of the eminent artists who draw on wood engrave their own designs. It is consequently difficult to determine the relative contributions to the total excellence of the brilliant wood engraving of the present day which have been made respectively by the draughtsman and the engraver. The importance of division of labor is so well understood that the draughtsman and engraver are seldom the same person. Some of the best painters draw on blocks for engravers, whose work is to give an adequate representation of the design. Birket Foster, Harrison Weir, John Tenniel, Gilbert Maclise, Stanfield, Leech, Doyle, Creswick, either painters or professional draughtsmen on wood, have been interpreted by Evans, Vizitelly, Greenaway, Palmer, Wright, Dalziel, Folkard, Thomas, Swan, and Williams. (A long list of designers and engravers on wood will be found at the end of the eighth chapter of JACKSON and CHATTO'S "History of Wood Engraving.")

The origin of the art of metal engraving has been disputed. Germany claims that the oldest dated specimens are by German artists. Italy claims the invention for Finiguerra, and the claim of Italy is now generally acquiesced in. Maso Finiguerra was a Florentine goldsmith, and according to Vasari, about A. D. 1460, having engraved a metal plate to receive enamel for ornamental use, poured on it some melted sulphur to take a cast, when he observed that the dirt in the incisions had adhered to the sulphur, making a picture in black. He thereupon rubbed ink into the lines of the engraving, and took an impression with wet paper. Since Vasari's time it has been well established that Finiguerra took impressions as early as 1450, and possibly 1445. Baccio Baldini, another Florentine goldsmith, seems to have learned the art from Finiguerra, and executed some plates, among which were nineteen which appeared in an edition of Dante published at Florence in 1481. The first book illustrated with copper plates was "Il Monte Sancto di Dio," published at Florence in 1477, containing three large plates, which are probably by Baldini. The art advanced rapidly to its highest state in Italy. In the commencement of the sixteenth century there were numerous copperplate engravers of great eminence in Italy, at the head of whom stood Marc Antonio Raimondi, whose works mark an important era in Italian engraving, and good impressions of whose prints are now valued at fabulous prices. He obtained the friendship of Raphael, and engraved under the painter's own eye very many of his works. His handling is peculiar, and though his engravings are deficient in "color" and effective distribution of light and shadow, he still holds a position among the very ablest engravers of any time. His scholars, who worked with him while living, Marco of Ravenna and Agostino of Venice, succeeded him and perpetuated his style. Giorgio Ghisi, born in 1524 at Mantua, and Bonasoni of Bologna (1498–1570) were engravers of distinction, and also painters. Cornelius Cort, a Dutch engraver (born 1536, died 1578), removed to Italy, where he was brought under the influence of Titian, and introduced a better representation of chiaroscuro and a breadth of manner not before attained. Agostino Caracci (born 1558 at Bologna, died 1602) was a pupil of Cort, and engraved a large number of plates, attaining high reputation, especially for his drawing. Martin Rota, a Dalmatian, whose prints range from 1558 to 1586, was an imitator of the school of Cort. Agostino Caracci, already named, Spagnaletto Guercino, Carlo Maratti, Guido Reni, Salvator Rosa, Claude Lorrain, Canaletti, and Piranesi were also known as painter-engravers, and maintained the reputation of this branch of Italian art. In later years, Volpato, Raphael Morghen, Toschi, and Longhi have produced works representing the great masters of Italy, which take a higher rank relatively than contemporary Italian painting.

Copperplate engraving seems to have been practised in Germany in the middle of the fifteenth century, and German work of the latter part of that century is superior to the Italian. Prints are extant with signatures of unknown artists which antedate those of artists who are known. Martin Schoen (or Schoengauer) of Colmar is regarded as the father of the art in Germany. The dates of his birth and death are in dispute, but his work was in the last quarter of the fifteenth century. He executed a large number of prints which are extant, and of which good impressions are highly prized. He was contemporary with many other copperplate engravers, and seems to have lived until the time of Dürer. The art reached high excellence in Germany in the time of Dürer (who died 1528). Marc Antonio in Italy confessed his indebtedness to Germany by reproducing in facsimile a considerable number of the works of Dürer. Dürer was also, if not the inventor, one of the earliest practitioners, of the process of etching. The principal German engravers after Dürer are his pupil Aldegraver, the two Behams, Altdorfer, Bink, Penz, etc. But the German school proper soon became absorbed in that of Italy, losing its peculiar characteristics. Since the beginning of the nineteenth century, engraving, like all branches of literature and art, has made steady progress in Germany.

Among the large number of distinguished men a few only can be named. C. F. Müller, though he died at thirty-three, is reckoned among the ablest engravers of all time. His "Madonna di San Sisto" is unrivalled. Steinla has a very high repute. The revival of the old religious style of art by Cornelius, Overbeck, and Kaulbach has had its effect upon engraving, and produced a peculiar style of handling, marked by the simplicity, purity, and religious feeling of the great painters just named. Amsler, the Felsings, Merz, and Mandel, though some of them may be charged with mannerism, are artists of great truthfulness and power.

France did not accept copperplate engraving at an early period, and hence contributed little to the early history of the art. The earliest engravings on metal which take rank in history are a collection due to artists employed in the decoration of the palace of Fontainebleau, about the middle of the sixteenth century. A large number of these are described by Bartsch under the name of the school of Fontainebleau. Most of them are anonymous, though they are thought to be the work of the painters themselves. The real history of the French school, as it is ordinarily understood, begins with the administration of Colbert, under Louis XIV. Among those we may name the Audran family, of whom Gerard is by far the ablest. He is said to be the first who united line engraving and etching in the same plate. Gerard Edelinck, though born at Antwerp, is placed in the French school. His facility and skill in execution were remarkable, and he carried "color" in engraving to a perfection never before reached. Nanteuil, the three Drevets, Callot (remarkable as an etcher), Leclerc, Chereau, Beauvarlet, Dupuis, not to name others, produced works in large numbers which are marked with great excellence and power. Wille, though a German by birth, belongs to this school, and is specially noted for his skill in imitating particular objects and articles of dress. It must be admitted that this school allowed their mechanical dexterity to lead them away from the higher ends of artistic expression. French engravers of the present day devote themselves in a great degree to the reproduction of modern paintings. Among these are Desnoyers, who died in 1857, Prevost, Forster, Richehomme, Lignon, Gerard, Prudhomme, C. R. J. François, and Girardet. There is now a society of etchers in Paris, which has published a series of yearly volumes which contain many etchings of great spirit and beauty. Lalanne, Calame, Meryon, Jacquement, and Hillemacher stand out among other names as etchers of high reputation.

Holland and Belgium have been prolific in engravers. The earliest of note is Lucas von Leyden. He was a contemporary of Albert Dürer, born in 1494. The Sadeler family and Abraham Bloemart carried forward the art, while Goltzius, Lucas Kilian, and Saerendam maintained the reputation early acquired by their masters. A class of engravers gathered around Rubens who profited by his suggestions. Among these are the Bolswerts, Vosterman, Paul Pontius, and Peter de Jode the younger. As painter-engravers we may name the incomparable Rembrandt, Ostade, Waterloo, Swanenelt, Paul Potter, Berghem, Karel du Jardin, Everdingen, and De Hooghe. These produced their effects mainly by etching, and as they engraved their own designs, their works have a constant artistic value as the autograph expressions of men of genius.

England seems to have had no great artists in wood or metal until a late period. It is probable that some rude wood-cuts were executed there in the fifteenth century, but the best illustrated books then published were illustrated by cuts imported from the Continent until the seventeenth century. The art of mezzotint engraving, in which English artists have greatly excelled, was introduced into England at the time of the Restoration. Hollar, a Bohemian by birth, was among the first English engravers of European reputation. William Faithorne first made mezzotint engraving popular in England. George Vertue, Vivares, and John Brown maintained the reputation of the art till the time of Strange. Strange was born in the Orkneys in 1721, and died in 1792. He was the father of line engraving in England. In this branch he reached at a bound the very highest point of excellence. Good impressions of his works are now sought for at high prices by all intelligent collectors. Woollett (born in 1735) is another engraver of high rank, especially in landscape. Sharpe has a high reputation in portrait engraving. McArdell, Green, and Earlom carried mezzotint engraving to high perfection. Etching has of late been revived in England, and the attention of the public has been attracted to it by the brilliant work of P. G. Hamerton, already mentioned. Turner exercised his genius in etching. Ruskin, his eulogist, has etched many of the illustrations of his works. Whistler, an American by birth, has achieved a high reputation in this branch of art. Haden, an amateur artist, has been given a very high position by Hamerton. Hamerton himself, in the pages of the "Portfolio," has given many pleasing illustrations of his devotion to this department of engraving, while his writings are likely to add greatly to its popularity among connoisseurs. Cruikshank and Doyle have been known as etchers, but have made the art subservient to caricature.

Engraving in Spain did not flourish until about the middle of the eighteenth century. A considerable number of Spanish engravers are given by historians of the art, but their works are not widely known beyond their own country. Carmona (born in Madrid in 1740) and his pupil, Selma, are names of special distinction.

Unless it be in the department of banknote engraving, Americans have not developed anything which may be called a school of the art. In the department named they are unrivalled, and have shown mechanical and artistic skill which, with proper patronage from the public, would command success in any sphere of the art. Wood engraving has taken relatively a higher rank than the other processes. But it is difficult without doing injustice to make critical estimates of artists of merit who may not have reached their highest degree of excellence, and we forbear to make selections.

The place of engraving in the general study of art is important. It interprets all the fundamental ideas of painting with the exception of color. This, within certain limits, it can suggest, if it cannot imitate. Printing in colors, even if the imitation be mechanical, tends to develop a taste for better things. Autograph engravings, or etchings from artists of distinction, enable the art-student or amateur to study in his own lines the artist's chosen expressions for his thought. In a country like ours, in which access to large collections of paintings is not possible, engraving furnishes the readiest, cheapest, and most practicable means of studying the history and growth of the arts of design in all departments. Architecture, sculpture, and pottery are alike dependent upon engraving for making their results intimately known to the great majority of those interested in their study. Relatively to art in general it sustains the same relation as does printing to literature. It makes the best ideas of the few available for the elevation of the many. As a means of popular education in art, engravings stand unrivalled. No lover of elegant culture can fail to rejoice that so many large and valuable collections of engravings are in the process of formation in all parts of our country.

The literature of the subject is extensive. The collector will find catalogues of the works of the most eminent engravers published as separate volumes, and often many catalogues of the same engraver by various editors. He will find general catalogues of all the important engravers, as "Le Peintre-Graveur" of Bartsch and the "Kunstler-Lexicon" of Nagler. (We append the titles of various authorities which are of most importance to the student of the art: Duplessis, Georges, "Essai de Bibliographie contenant l'indication des ouvrages relatifs a l'histoire de la gravure et des graveurs," Paris, 1862; Ottley, "Inquiry into the Origin and Early History of Engraving," 2 vols., London, 1816; Palgrave, F. T., "Essay on the First Century of Italian Engraving" (in Kugler's "Hand-book of Painting," vol. ii.); J. D. Passavant, "Le Peintre-graveur," 6 tom., Leipsic, 1860–66; Bartsch, "Anleitung zur Kupferstichkunde," 2 bde., Weiss., 1821; Dusmenil, Robert, "Le Peintre-graveur Français," 10 tom., Paris, 1835–69; Brulliot, François, "Dictionnaire des Monogrammes, Marques figurées, Lettres Initiales," etc., Munich, 1832; Bartsch, Adam, "Le Peintre-graveur," 21 vols. and supplement, Vienna, 1803–21; Bryan, Michael, "A Biographical and Critical Dictionary of Painters and Engravers," new ed. by George Stanley, London, 1858; Jackson and Chatto, "A Treatise on Wood Engraving," London, 1861; Heinecken, "Idée Générale d'une collection complette d'estampes," etc., Leipsic, 1771; "Biographical History of the Fine Arts," Spooner, New York, 1845; Nagler, "Neue Allgemeine Kunstler-Lexicon," etc., 18 vols., Munich, 1835–48; Hamerton's "Etching and Etchers," London, 1866.)

M. B. Anderson.

Engraving Maps and Charts.—The best maps are engraved on copper, and sometimes on steel, which is, however, at present not much used, being liable to rust. The design is drawn on paper, and is transferred to tracing paper by going over the lines of the drawing with a material composed of Frankfort black and urine. The design is then divided both ways through the centre by lines drawn to match similar lines on the copper plate.

The copper is burnished after all the imperfections are removed. It is then "coaled" over with mahogany charcoal, and is next rubbed with oil and rotten-stone, and afterwards thoroughly washed with soap and water and dried, and then rubbed with whiting. The plate is then warmed and white wax is applied. The wax having melted, a folded

rag is drawn across it until the wax is of even thickness. The plate is cooled, and is then ready for use. The tracing paper, with the design upon it, is laid face downward upon the waxed surface. The tracing paper is rubbed with the burnisher, which causes the transfer of the lines to the wax. The coast-lines, rivers, railways, and common roads are engraved upon the copper by suitable gravers, towns are indicated by the stroke of a punch, boundary-lines are run over by the roulette, and the lines are finished after the wax is removed. Topographic marks (mountains, etc.) are dry-pointed lightly. The wax is then removed by melting; the cut lines are scraped to remove the "burr;" the plate is coaled and rubbed. The topography, coast or water lines, and the necessary lettering are next cut. After this, degree-lines (parallels, meridians, etc.) are ruled in. The mountains or topography are usually bitten-in by acid (see paragraph "Etching" in the article ENGRAVING), the heavy shadings being commonly added by means of the square graver. The tools employed are the eye-glass, burnisher, scraper, roulette, gouge, callipers, rules, gauges, gravers, punches, etc.

At present, maps are not printed directly from the copper plates, but the printing is generally done by the lithographic process, as follows: The copper plate is used for making an impression upon autographic paper, prepared with a coating of starch, gum, etc. in variable proportions. The ink used is a mixture of ordinary lithographic ink with oil, soap, tallow, varnish, etc. The impression is made with great care upon the starched side of the paper. This paper, carefully moistened, is laid upon a polished lithographic stone, "backed" with great care by folds of paper, and then pressed with great force, in a lithographic press, upon the stone. The paper, on being stripped away, leaves, if the work is well done, all its lines beautifully transferred to the stone. After washing and drying, the stone is used for printing as in ordinary lithography. From two to five thousand first-class impressions can be taken from one transfer if skilfully done.

Lithography proper [from the Gr. λίθος, a "stone," and γράφω, to "write"] may be considered as a branch of engraving. It owes its existence to the fact that certain slates of the middle oolite (found in the highest perfection at Solenhofen in Bavaria) and various subcarboniferous and other limestones of greatly inferior quality, found in Missouri, Canada, and other regions, though compact, have a surface of somewhat open grain, capable of absorbing and retaining water, oils, and inks made with fats, etc. Now, if parts of the smooth stone be covered with a drawing in oil, the remaining parts can be wet without wetting the oiled parts. If "fat" ink be now applied to the stone, it will adhere to the dry parts, but not to the wet. By alternately wetting and inking the stone, a great number of impressions can be taken.

There are several methods of drawing upon the stone, besides the transferring process mentioned in the paragraph on map engraving. Drawing is done by the crayon, pen, or brush. The stone is often cut by the needle or dry-point, the latter being true engraving. Engraved stone, however, though capable of giving fine results if great care be used, is ordinarily very much inferior to engraving upon steel or copper plates.

Color-printing on stone, or chromo-lithography, has of late years been employed with surprising success in the production of cheap imitations of oil paintings; for although it is true that the greater part of this kind of imitation is inferior in quality, the best examples are in reality artistic, and are highly admirable. Each color is applied by using a different stone.

In all processes, except in stone engraving with the dry-point, relief is generally given to the design by washing the stone in dilute acid, which attacks the parts unprotected by oil, and thus, when skilfully handled, gives increased clearness to the impression. One of the latest inventions in this line is photo-lithography.

ENGRAVING STEEL AND COPPER PLATES.—The origin of engraving on metal, from which printed impressions were taken, dates A. D. 1450. In that year, Maso Finiguerra, an engraver on gold and silver plate, a native of Florence, being engaged on an engraving of a "pax" ordered by the brothers of the church of St. John, and wishing to see the effect of his work, filled the lines cut by his graver with a mixture of oil and soot. A pile of damp linen was, by chance, placed upon the silver plate thus prepared, and the cut lines filled with the black mixture were transferred upon the linen. The original plate of the "Coronation of the Virgin," a niello engraved in 1452 by Maso Finiguerra, is in the Uffizi Gallery at Florence, and the only known impression from it is carefully preserved in the Bibliothèque de Paris.

The first engravings on metal plates for the purpose of printing therefrom, executed in Italy, are found in the "Monte Santo di Dio" (1477) and in an edition of Dante (1481). Sandro Botticelli, a great painter, supplied the designs and assisted in the engraving; but the oldest copperplate print in existence—a German one—bears the date of 1461. Before the close of the fifteenth century many books were published which were filled with illustrations and maps printed from metal plates. The graver was skilfully used by many eminent painters, such as Albert Dürer, Rembrandt, and Vandyke, while Raphael had Marc Antonio and other Italian engravers transfer his designs to plates for reproduction. The discovery of etching—that is, where the work is "bitten in" on the plate by acid—is attributed to both Parmegiano and to Albert Dürer. The spread of the art of engraving on metal was rapid, and it was known in England as early as 1483. The earlier styles or processes were confined to *line*, executed entirely with the graver, and to *etching*, done by a sharp point or needle. The style called *mezzotinto* or *mezzotint* was probably invented about 1600, for François Aspruck engraved in 1601, by means of a process resembling mezzotint, a series of thirteen plates of Christ and the apostles, and one of Venus and Cupid. In the year 1643, Louis of Siegen, a German officer, employed it for his portrait of Amelia Elizabeth, the landgravine of Hesse-Cassel; and Prince Rupert, the nephew of Charles I., was led to its discovery when living in retirement at Brussels after the year 1649, through observing a sentinel scraping the rust from his gun-barrel; yet the honor of its first invention cannot be ascribed to him. The *aquatint* process, which resembles mezzotint in its results, was invented by J. B. Leprince about 1787. The *stipple* or dot style has been used for a long time in combination with other styles of engraving; it is chiefly employed in the rendering of flesh and in producing copies of statuary. Another style, termed the *chalk* style, has its use in representing sketchy subjects done with the pencil, chalk, or crayon.

Up to the year 1815—except a single print in London in 1805—copper was exclusively used to engrave upon. *Engraving on steel* is an American invention, due to Jacob Perkins of Newburyport, Mass. In 1814 he went to Philadelphia, where he associated himself with an engraving firm for the purpose of carrying his invention into practical operation. The processes for engraving on steel or copper are similar, but the superiority of steel plates, in consequence of their hardness, the sharpness and piquancy of the printed impressions therefrom, and the great number of impressions that can be taken before the plate is worn, renders them preferable for engraving purposes, unless it be for letter engraving when small numbers are required to be taken from the plate.

Engraving on Steel, the Processes.—The plate on which the engraving is executed is ground and polished by the plate-maker until its mirror-like surface is free from all scratches or blemishes. The edges are bevelled, so that it may readily pass between the rollers of the printing-press when completed. An etching-ground is then laid upon the plate by the engraver. This ground consists of a mixture of burgundy pitch, rosin and asphaltum; it is applied to the heated plate by "dabbing" it over the surface; it resists acid, but great care must be taken in preventing any dust settling in the ground when heated, else when the acid is applied "false biting" of dust-specks will result. When the ground is cold, the outline of the subject, prepared by finely-traced lines with the "dry-point" on gelatine paper, is transferred upon the ground by laying thereon the traced side of the paper filled with scrapings from a lead-pencil or red chalk, and the back of the paper gently rubbed with a burnisher. The etching process is then commenced by cutting the lines or dots desired with the dry-point through the etching-ground. The width between the lines or dots is carefully studied, and laid in with reference to the final result when "bitten-in." When completed, a wall of wax is placed around the edges of the plate to prevent the acid from running off, and the "biting-in" process is begun by pouring on the acid (generally one part of nitric acid to three parts of water), which is immediately poured off for the more delicate biting, and water washed over the work and removed, and the surface blown dry with a common bellows. The delicate work is then "stopped out" with asphaltum varnish, and the biting resumed until the darkest or heaviest lines are bitten sufficiently. The ground is then removed with turpentine, and such parts of the work needing further biting may be "re-bitten" by laying a re-biting ground dexterously dabbed on the surface, so as to leave each line or dot perfectly clean; and then proceed with the acid as at first. Most plates are etched at first, whether completed in line, mezzotint, or stipple style, the style of the etching being varied according to the manner in which the work is to be finished. *Pure line engraving* is produced by cutting lines, broken lines, or dots on the steel with a tool called the graver; but this style is now

rarely ever used except in banknote engraving, the vignettes of which are engraved in this style, on die steel, which is hardened for transferring to other steel plates; and so any number of copies of the original plate may be duplicated on other softer plates, which, when hardened, are used in printing the engravings. *Line-and-stipple* engraving is rendered by cutting or etching the lines on draperies, and dotting (stippling) the lighter parts of draperies and flesh with the graver or dry-point. *Mezzotint* engraving is produced by laying a "mezzotint ground" over the surface of the etched subject by means of a "rocking-tool" (sometimes termed a "cradle") with fine teeth, which are impressed into the plate by a rocking motion of the tool; after rocking over the plate a great number of "ways," the surface becomes filled with fine dots, which, if printed from, would give a perfectly black tint. The high lights, half tints, and gradations are then "scraped" out with a tool termed the "scraper," and the work finished with the burnisher. This style produces a very soft and pleasing engraving, and with a well-prepared etching of under work in line and-stipple is extensively used by some engravers in producing the finest engravings. It is more generally known as the *mixed* style—line, mezzotint, and stipple. Pure mezzotint engraving has become quite obsolete, as it will not admit of being printed from in large quantities, but when mixed with other styles from 30,000 to 50,000 fair impressions may be taken from a single plate. *Aquatint* engraving is often confounded with mezzotint from its resemblance to it, but the process is quite different. An aquatint ground is laid on the surface of the plate by pouring a resinous substance which has the peculiarity of separating its particles so as to leave bare spaces, or eccentric rings left bare, which when exposed to acid are corroded. The laying of the ground requires the greatest dexterity and judgment, and must be done in a dry atmosphere. The tone produced resembles that of a washed drawing in India ink, soft and harmonious. Aquatint engraving is used for reproducing geological specimens, as fossils, shells, stones, etc., with great success.

Steel and Copper Plate Printing.—When the engraver has completed his work, a proof of the same is taken, and usually on India paper, which has the quality of taking up the ink more perfectly from the engraved lines or dots, and leaving the precise tone of the work, than ordinary white plate paper. Proofs on India paper are considered much more valuable than plain impressions. The process of plate-printing is as follows, viz.: the paper is "wet down" in alternate layers of wet and dry sheets, and allowed to moisten evenly. Much depends on the even moisture of the paper in obtaining good impressions. The plate is warmed by soapstone plates heated underneath, and the ink rolled upon its surface. It is then removed, and the ink "wiped," by several rags or pieces of millinet, from the surface; and finally the entire surface of the plate is polished with whiting on the palm of the hand. The plate is then placed on the press, consisting of a bed-piece running between two heavy iron rollers, with blankets around the upper roller to prevent injury to the plate; and a sheet of the dampened paper adjusted carefully to the inked surface of the plate, and passed through the press. The impression is then dried, and pressed in a "standing press," to give the surface of the paper its proper finish or polish.

GEO. E. PERINE, *Engraver on Steel*, New York City.

Engraving, Bank-note, embraces the chief characteristics of general engraving, with a number of special processes peculiar to itself. It is a combination of the highest style of the art and the greatest perfection in machinery and in the details of the business, requiring a system of accounts and checks, together with discipline and watchfulness, almost unknown in any other pursuit. The variety of its work makes necessary the employment of the best talent in all branches, and the constant demand for something new wherewith to baffle illegitimate imitation brings into use the inventive faculties and skill of the best experts in the business.

Bank-note or vignette engraving, while it is in the order of line engraving and etching as otherwise described, requires special treatment to render it useful for the purposes designed. Boldness must be produced without destroying the delicacy of the work, the object being to render the subject capable of reproduction by machinery without losing in the process the faintest line which the genius of the artist conceived necessary for the perfection of the picture. The great expense attending the execution of these engravings makes this reproduction necessary, so that a limited number of vignettes and pieces of lathe-work, variously combined for different notes, may, in effect, be as practically distinct from each other as if special work had been used for each. The invention of Jacob Perkins, known as the "transfer press," here becomes most potent, and, combined with a thorough knowledge of the manufacture of steel and its treatment in the various processes of hardening and softening, the power to reproduce the original engraving to an unlimited extent is effected.

The original engraving, or "bed piece," as technically known, is hardened to a degree rendering it capable of resisting a pressure of twenty tons without breaking the steel or even crushing the delicate engraving. The experience required to determine the precise temperature necessary for complete and perfect hardening here becomes manifest, when it is understood that a degree of heat beyond the extent required will destroy the engraving and render useless the labor of weeks. The bed-piece being properly hardened, a polished steel cylinder or "roll" is passed over the bed-piece, and the engraving "taken up" on the roll in relief. This roll is then hardened, and becomes the "die," to be used indefinitely.

Another and most important adjunct to the business of bank-note engraving is the geometrical lathe. This machine is used in making the "counters" on bank-notes, which are the pieces of work usually containing the denominations. The borders and the backs of notes are also made up of this class of engraving. The geometrical lathe is the invention of Asa Spencer of Philadelphia in the early part of the present century, whose machine, however, merely made an eccentric motion, producing a waved line. Cyrus Durand improved upon this, and added a second motion. Other improvements followed to the extent of five distinct motions, beyond which no further progress was made until within a few years past, when, under the manipulation of C. W. Dickinson of Newark, N. J., the power and usefulness of the invention have been wonderfully developed. The form of the work to be produced is the mental conception of the artist, followed by an algebraic calculation. The machine is then arranged to meet the result of this calculation, and, so far as the machine is concerned, success is certain. The piece of steel to be operated upon is attached to the "chuck" of the machine, which is movable, its motion varying in accordance with the pattern to be produced. An examination of any of these lathe-cuttings reveals to the eye a number of different forms of lines, apparently added one after another, and yet it is really one unbroken line, which, if stretched out, would occupy many thousand feet. The beautiful patterns thus produced by the interlacing of these lines are truly wonderful, and the accuracy of the machine is no less marvellous. To produce the proper depth of line the point often travels at least twenty-five times through the grooves made by it, and frequently in such close proximity to other portions of the same groove that the dividing space is almost imperceptible; and yet the movement is so true that these spaces are never broken down or unnecessarily encroached upon. The piece of steel when completed is hardened, and the "die" produced as before described.

A not unimportant feature of bank-note engraving is the lettering and ornamentation, which are as distinct from vignette engraving as either is from lathe-work. The arrangement of the wording of bank-notes, the style and symmetry of the individual letters, and the necessary ornamental work to blend the whole into perfect harmony, bring into action the best cultivated taste and capacity for designing. In the leading bank-note establishments much of the lettering and ornamentation is done by machinery—inventions conceived and built by their own mechanicians, and used exclusively in the execution of their own work.

Bank-note engraving, in its present perfection, is the result of improvements and skill encouraged and fostered exclusively in the U. S.; and in this particular branch of the arts our country is supreme, sending its handiwork to all parts of the civilized world. The American tourist abroad is often pleasantly reminded of home when the well-known imprint of the "American Bank-note Company, New York," meets his eye on the paper issues of the country in which he is travelling. The advantage of thus using the best available talent in the production of these issues is fast gaining ground wherever currency of this nature is required, and the superiority of the American manufacture is everywhere admitted.

C. L. VAN ZANDT.

Engros'sing [from the Fr. *grossoyer*, to "write in a large hand"], the writing of a deed in proper legible characters. Among lawyers it signifies especially the copying of any instrument or document on parchment or stamped paper. In the English statute law engrossing signifies the purchase of large quantities of any commodity, in order to sell it again at an exorbitant price, or in order to raise the market-price of the same.

Eng'stlen Alp, a beautiful place of Alpine resort, just S. W. of Engelberg, canton of Unterwalden, Switzerland. It rises 6092 feet, and its beautiful pastures, with the neighboring lake, Engstlensee, the Wunderbrunnen (an intermittent spring), the falls of the Engstlenbach, the glaciers near

at hand, and the loftier snow-clad peaks around, render it a place of great attractiveness to tourists.

Eng'ström (Johan), a Swedish poet, novelist, traveller, and physician, born April 7, 1794, at Kærnebo, in the government of Kalmar, received his medical license in 1817, and until 1825 was employed as an army-surgeon. Author of "Resa genom Norrland och Lappland" (1834); "Resa genom södra Lappland, Jemtland, Trondhem och Dalarne" (1835); "Nordiska Dikter af Eivin" (1821); "Eols Harpan" (1830); "Förbundsbröderna" (1833–34); "Nybyggarne" (1838); "Björn Ulftand" (1840).

Engue'ra, a town of Spain, in the province of Valencia, 46 miles S. W. of Valencia, has manufactures of linen and woollen goods. Pop. 5939.

Enharmon'ic [Gr. *ἐν*, "in," and *ἁρμονία*, "harmony," "concord"], in music, one of the three genera (chromatic, diatonic, and enharmonic) of ancient music. The enharmonic genus of the Greeks was distinguished by the use of small intervals or quarter tones. In modern music, intervals much less than a semitone owe their origin to the slight difference of pitch which the same (nominal) note takes according as it is adjusted to one or another fundamental note or *tonic*. Thus C♯ and D♭ are, at least on keyed instruments, practically the same note, though strictly the former should be produced by $\frac{1}{15}$ of the whole string sounding; the latter, by $\frac{2}{15}$. The passage from one to another of these intervals is called an "enharmonic change," and a change of key so effected, an "enharmonic modulation."

Enig'ma [Gr. *αἴνιγμα*, from *αἰνίσσομαι*, to "speak darkly" (from *αἶνος*, a "fable"); Fr. *énigme*], an obscure question; a riddle; a proposition put in obscure or ambiguous terms to puzzle or exercise the ingenuity in discovering its meaning. Formerly it was deemed a matter of such importance that Eastern monarchs sometimes sent embassies for the solution of enigmas. Among the famous enigmas of antiquity were that which Samson proposed to the Philistines and that which the Sphinx propounded to Œdipus. (See Sphinx.)

Enkhuysen, ĕnk-hoi'sẹn, or **Enkhuisen,** a fortified seaport-town of the Netherlands, is in the province of North Holland, on the Zuyder Zee, 30 miles N. E. of Amsterdam. It has a fine town-hall, several churches, a cannon-foundry, and several shipbuilding yards. Butter, cheese, timber, and fish are exported hence. This was once a town of 40,000 inhabitants, and had a great herring-fleet, but the silting up of its harbor has wrought its decay. It still has a fine appearance from without. Its town-house, built in 1588, and the Westerkerk, are the most remarkable buildings. Here Paul Potter, the great painter, was born in 1625. It was founded in 1200, and was sometimes called Enchusa. Pop. 5625.

Enlist'ment, the voluntary enrolment of men in the military or naval service. In the U. S. service enlistments are under a detailed officer styled superintendent of the general recruiting service, assisted by other officers, each detailed for two years by the war department. The superintendent's office is in New York. Men are enlisted for five years' duty in every branch of service. Recruits are enlisted (1874) at twenty rendezvous, one at each of the following cities: Albany, Baltimore, Boston, Brooklyn, Buffalo, Chicago, Cincinnati, Cleveland, Detroit, Dubuque, Elmira (N. Y.), Evansville (Ind.), Indianapolis, Jersey City, Louisville, New York City (two rendezvous), Philadelphia, Springfield (Ill.), and St. Louis. They are sent for examination and training to two dépôts—one at Fort Columbus, Governor's Island (N. Y. Harbor), and one at Newport Barracks, Ky. Thence they are assigned to regiments by order of the war department.

En'na, an ancient city of Sicily, very near the centre of the island, on a lofty hill, almost inaccessible except at a few points. It was anciently a place of great importance. Its site is now occupied by the decayed town of Castro Giovanni (which see). Enna is memorable as a seat of the ancient worship of Demeter, and the shore of a small lake near by was the scene of the mythical rape of Persephone, a favorite subject with poets and artists. Comparatively few remains of the ancient city have survived the ravages of the Greek, Punic, Roman, servile, Arabian, and Norman conquests.

En'neagon [from the Gr. *ἐννέα*, "nine," and *γωνία*, an "angle"], a plane rectilineal figure having nine sides and angles. The area of a regular or equilateral enneagon is approximately 6.18182 times that of the square of one of its sides.

Ennean'dria [from the Gr. *ἐννέα*, "nine," and *ἀνήρ*, *ἀνδρός*, a "man" or "male"], the ninth class of plants in the artificial system of Linnæus, so called because each flower has nine stems. The term *enneandrous* is applied to these plants or flowers, which are not numerous, and the distinction itself is unimportant; accordingly, the name is now seldom used.

En'nel, a picturesque lake of Ireland, in the county of Westmeath. From it flows the river Brosna. It contains some wooded islands, and its shores are adorned with fine residences. It is near Mullingar, the county-seat.

En'nemo'ser (Joseph), M. D., a German writer on physiology and animal magnetism, was born in the Tyrol Nov. 15, 1787. He fought against Napoleon in 1813 and 1814, and graduated as M. D. at Berlin in 1816. He became in 1820 professor of medicine at Bonn, and removed in 1841 to Munich, where he practised with success. Among his works are "Magnetism in its Relations to Nature and Religion" (1842) and "History of Magnetism" (1844), the first volume of which (the "History of Magic") was translated into English by William Howitt (1854). D. in 1854.

En'nerdale Lake, a picturesque sheet of water in the mountain-region of Cumberland, England, 7 miles N. E. of Egremont. It is an expansion of the river Eken, 2½ miles long and less than 1 mile wide.

En'nis, a market-town of Ireland, the capital of the county of Clare, on the river Fergus, 20 miles W. N. W. of Limerick. It has a town-hall, a classical school called Ennis College, and the ruins of an abbey founded in 1240. It returns one member to Parliament. Here is a valuable limestone quarry. Ennis has a lunatic asylum, a jail, an infirmary, a hospital, a public library, a fine court-house, three banks, and two newspapers, a brisk trade and some manufactures, and a colossal statue of O'Connell by Cahill. Four bridges cross the Fergus, and railways extend to Limerick and Athenry. Ennis is one of the see-towns of the diocese of Killaloe (Roman Catholic). P. in 1871, 6101.

Ennis, a post-village of Ellis co., Tex., on the Houston and Texas Central R. R., 20 miles N. by W. of Corsicana.

En'niscorthy, a market-town of Ireland, in the county of Wexford, on the river Slaney, 14 miles N. N. W. of Wexford. It has a splendid Roman Catholic church, and a stately Norman castle many centuries old, but still entire. It has a large trade in grain, is at the head of barge navigation, is connected by railway with Dublin and Wexford, has a convent, five churches and chapels, two banks, two weekly newspapers, and a lunatic asylum. The Irish rebels took it by storm and burned it in 1798. Pop. in 1871, 5804.

En'niskillen, a parliamentary borough of Ireland, the capital of the county of Fermanagh, is finely situated on the river Erne, which connects the Upper and Lower Lough Erne, about 75 miles W. S. W. of Belfast. It has a town-hall, two barracks, six churches and chapels, three newspapers, a court-house, a prison, an infirmary, tanneries, straw-hat works, a flax-market, a market for corn, pork, and butter, two forts, a linen hall, and manufactures of cutlery. There are handsome mansions and beautiful scenery in the vicinity. The people of Enniskillen warmly supported the Protestant cause in 1689. Here the troops of William III. defeated those of James II. in that year. It is connected by railway with Dundalk, Londonderry, and Bundoran, and steamers ply on the Erne. P. in 1871, 5906.

Enniskillen, a post-village of Queens co., N. B., on the European and North American Railway, equidistant from Fredericton and St. John, 34 miles from each. It has a good lumber-trade.

Enniskillen, Earls of (1789), Viscounts Enniskillen, 1776; Barons Mountflorence (Ireland, 1760), have seats in Parliament as Barons Grinstead (United Kingdom, 1815).—William Willoughby **Cole,** third earl, D. C. L., LL.D., F. R. S., was born Jan. 25, 1807, and succeeded to his father's title in 1840. He was educated at Oxford, and before 1840 was distinguished in the House of Commons as Lord Cole, and acted in the Conservative interest.

En'nisville (post-office name Innisville), a village of Drummond township, Lanark co., Ontario, Canada, on a navigable stream called the Mississippi. A steamboat plies to Carleton Place, 9 miles distant.

En'nius (Quintus), a celebrated Roman epic poet, born of a Greek family at Rudiæ, in Calabria, about 240 B. C. He acquired the rights and privileges of a Roman citizen, and enjoyed the friendship and patronage of Cato and Scipio Africanus. It is said that he supported himself by teaching the Greek language. He contributed greatly to the formation of the national literature of Rome, and was the first great Latin poet. His most important work was an historical epic poem entitled "The Annals," which was for many years the most popular poem in the language. His works, which included tragedies and comedies, are all lost except some fragments. His poetry was admired by Lucretius and by

Cicero, who often quotes him. He died in 169 B. C. Among the best editions of his works are those by Spangenberg (1825) and Vahlen (1869). (See SELLAR, "Roman Poets of the Republic," chap. iv.; Vossius, "De Poetis Latinis.")

Enns, or **Ens** (anc. *An'isus* or *An'asus*), a river of Austria, rises in the crown-land of Salzburg, 11 miles S. of Radstadt. It flows through Styria, forms the boundary between Upper and Lower Austria, and enters the Danube 11 miles below Lintz. Length, about 120 miles.

Enns, a town of Austria, on the Danube, at or near the mouth of the Enns, about 96 miles W. of Vienna. It has manufactures of iron, steel, and cotton. It was the headquarters of Napoleon in 1809. Pop. in 1869, 3784.

E'noch, or **He'noch** [Heb., "initiated" or "teacher"], the name of five persons mentioned in the sacred books (canonical and apocryphal) of the Hebrews. The second in the order of time, and the most important, was "the seventh from Adam," who "prophesied," and was translated at the age of 365. (Gen. v. 23.)

Enoch, Book of, quoted by the apostle Jude (vv. 14, 15), an apocryphal book of 108 chapters, of unknown authorship and of uncertain date, critical conjecture ranging from 144 B. C. to 135 A. D. It was probably written in Hebrew by a Palestinian. The early Christian Fathers used it, but for some centuries only fragments of it were known to European scholars, till in 1773 James Bruce brought home with him from Africa three copies of an Ethiopic version of it, made apparently from the Greek about 350 or 400 A. D. It was published in 1838 by Archbishop Laurence, who had previously (in 1821) published an English translation of it, and by Prof. Dillmann (1851). The book contains many curious passages, but its leading idea is that of Divine justice dealing sternly with sinners. Special works on the book of Enoch have been written by Ewald (1854), Philippi (1868), and others.

Enoch, a post-township of Noble co., O. Pop. 1362.

E'non, a post-township of Bullock co., Ala. Pop. 1748.

E'nos (anc. *Æ'nos* or *Ænus*), a seaport-town of European Turkey, in Roum Elee, on the Ægean Sea, at the mouth of the river Maritza (*Hebrus*), about 75 miles S. by W. from Adrianople, of which it is the port. Its harbor admits only small vessels. Pop. about 6500. Here is a small bay called the Gulf of Enos. *Enos* is mentioned by Homer in the "Iliad," book iv.

E'nos (ROGER), GENERAL, born in 1736, was a lieutenant-colonel in Arnold's Quebec expedition (1775), but by a council of war held on the Dead River in Maine was sent back to Cambridge with a part of the troops, on account of the lack of provisions. He commanded at Castleton, Vt., in 1781, and became afterwards a major-general of Vermont militia, and one of the first men of the State. Died at Colchester, Vt., Oct. 6, 1808.

E'nosburg, a township and post-village of Franklin co., Vt., on the eastern division of the Vermont Central R. R. It has nine churches, and manufactures of leather, carriages, lumber, woollens, and other goods. Pop. 2077.

Enrol'ment signifies in law the registering or entering of a document or lawful act in the rolls of the chancery or superior courts of common law or in the records of the quarter sessions. Such enrolment was rendered necessary in different cases by statute. In the reign of Henry VIII. of England a statute was enacted that no transfer of land should be effected by bargain and sale unless the deed were enrolled within six months after its date. A decree in chancery does not take full effect until it has been enrolled. Before the enrolment the cause may be removed to the court of appeal, which may reverse the decision, but after the enrolment it can only be heard in the House of Lords.

Ens (gen. **Entis**), a Latin term used in metaphysics to denote being, entity, or essence (Gr. τὸ ὄν). *Ens reale*, a positive or real being, is distinguished from *ens rationis*, which exists only in idea. The mediæval alchemists and pharmaceutists used the word *ens* in a variety of senses. Thus, they speak of the *ens Dei*, "the power of God;" *ens astrorum*, "the influence of the stars;" *ens morborum*, the "principle of diseases;" *ens de potentibus spiritibus*, the "activity of powerful spirits." *Ens primum*, the "first essence," was a hypothetical preparation believed to have power to transmute the metals. *Ens martis* was a certain preparation of iron; *ens veneris*, the "essence of Venus" (or copper), was cupric ammonio-chloride.

Enschede, ĕn'skā'dĕh, a frontier town of the Netherlands, province of Overyssel, about 90 miles E. by S. from Amsterdam. It has manufactures of cotton. Pop. in 1867, 5134.

Ensemble, ŏn'sŏmb'l', a French word signifying "together" or "the whole," is used to express the general effect produced by a picture or by the various parts of a musical performance: also the masses and details of a painting considered with relation to each other.

En'siform Car'tilage [Lat. *cartila'gensiformis*, from *ensis*, a "sword," and *forma*, "shape"], called also the **Xiphoid Cartilage** or **Ensiform Appendix,** in human anatomy, is the third and lowest piece of the sternum or breast bone. It is smaller than either the first piece (*manubrium*) or the second (*gladiolus*). It is of various form, usually more or less dagger-shaped, sometimes perforated, sometimes 2-pointed, and is usually cartilaginous until the seventeenth or eighteenth year, when a centre of ossification appears in its upper part, and the whole takes on, very slowly, a somewhat bony character. It appears to represent the united hæmal spines of those vertebræ to which the floating (eleventh and twelfth) ribs are attached.

En'sign [Lat. *insig'ne*, neut. of *insig'nis*, "remarkable," "striking" (from *in*, "in" or "for," and *signum*, a "sign"); Fr. *enseigne* or *drapeau*], the national flag or banner carried by a ship of war, and usually hoisted at the peak or on a flagstaff at the stern. Its chief purpose is to indicate the nationality of a ship when it meets another vessel at sea. In the navy of the U. S. the ensign is the national flag. All British men of war since 1864 carry the St. George's ensign—viz., a white ensign with a red cross, and a union-jack in the left-hand upper quarter. The English ensign is a red, white, or blue flag, having the union in the upper corner next the mast.

ENSIGN is the title of the lowest commissioned officer in the British army. He performs the usual duties of a subaltern. There are as many ensigns in a regiment of infantry as there are companies, and the junior of these carries the regimental colors.

ENSIGN in the U. S. navy is the eighth grade of commissioned officers, ranking below that of master and above that of midshipman. The highest pay is $1400 a year.

Ensinal', a county in the S. of Texas. Area, 1610 square miles. The Rio Nueces touches the north-eastern corner of this county, which is drained by several affluents of the Nueces. It is almost exclusively devoted to sheep and cattle ranges. Water and wood are scarce. Pop. 427.

Ens'ley, a post-township of Newaygo co., Mich. Pop. 606.

Ens Mar'tis [Lat.], (*i. e.* the "essence of Mars" (iron), an old alchemical name for the ammonio-chloride of iron, formerly used in medicine. It is an uncertain aperient and chalybeate tonic.

Entab'lature [Mod. Lat. *intabulamen'tum*, from *in*, "upon," and *tab'ula*, a "board" or "plank;" literally, "placing boards upon;" applied originally to the roofing of a house, and especially to the horizontal covering which rested upon the upright supports of a building], in architecture, the portion of a building between the columns and the roof, running round the edifice. It consists of architrave, frieze, and cornice. In ordinary building the term is applied to the course of masonry on a wall immediately below the roof.

Entail'. By this term is meant an estate in fee limited to certain classes of descendants. Thus, a fee simple would be regularly created by the word "heirs," as, for example, to "A and his heirs," and would descend to any heirs, however remote. An estate given to "A" and "the heirs of his body" would be confined to descendants. This is an example of the proper words to create an estate tail. The descent might be still more strictly confined, as to male issue or the issue born of some specified mother. The peculiar features of an entail depend upon a well-known English statute termed *De donis*, the regular effect of which was to confine the property to the specified mode of descent. The result was that the tenant in tail had the general characteristics of owner, except that he could not sell, and that the land could not be seized for his debt. The courts permitted the entail to be destroyed by a fictitious legal proceeding called a "fine," and more completely by another like proceeding called a "common recovery," instituted in behalf of the tenant. He could thus, if he saw fit, become absolute owner. The "common recovery" is now abolished by statute in England, and under certain limitations the tenant may resort to a conveyance called a "disentailing deed," and thus acquire a fee simple. In the United States words constituting an estate tail according to English law will usually be construed to create a fee simple, unless the property is given over to some other person on default of issue surviving the first taker; in which case the secondary gift would be upheld, and would take effect should no issue survive. This last point will be more fully noticed under the titles PERPETUITIES and REMOTENESS.

En'tasis [Gr.], a delicate and almost imperceptible swelling of the shaft of a column, is found in nearly all ancient Greek examples. It was adopted to prevent the shafts being strictly frusta of cones, in which case there would, by a simple optical law, be an incorrect impression made upon the eye as to the proportions of the column. The curve of the entasis was usually either part of a hyperbola or of a conchoid. It was one of the most delicate yet important of the refinements of Greek architecture, and has not been accurately attained in modern imitations. In the columns of the Parthenon the entasis amounts to $\frac{1}{550}$ of the whole height of the column.

Entel'echy [from ἐντελής, "perfect," and ἔχειν, to "have"] is a metaphysical term from the Aristotelian philosophy, denoting the fundamental idea of the whole system. Cicero defined this idea as *energy*, but the Greek philosophers who, in the fifteenth century, moved from Constantinople to Italy—and among them especially Argyropolus—ridiculed him for the definition, and gave *perfection* as the constituent element of the idea. Melanchthon, however, and Leibnitz, and all modern philosophers almost without exception, follow Cicero; and when the "Entelechy" of Aristotle is compared with the "Idea" of Plato or the "Absolute Negativität" of Hegel, or other fundamental ideas of other philosophical systems, it is evident that *energy* covers a much larger part of the Aristotelian idea than *perfection*. The abstract repose of the Platonic "Idea" is supplanted by the energy of reality in the Aristotelian "Entelechy;" its potentiality becomes actuality. Aristotle calls truth an idea, but the soul he defines as an ἐντελέχεια; and when Dr. Reid tells his readers that he can make no sense of this definition, he seems to forget that there are confessions which it is utterly unnecessary to make. The best explanations of the entelechy, and its relations to the whole system of Aristotelian philosophy, are given by Brandis in his "Aristoteles und seine Akademischen Zeitgenossen," Berlin, 1857, and by Thurot in his "Études sur Aristote," Paris, 1860.

Entel'lus, one of the mythical companions of Æneas. He was an aged hero of Troy or Sicily, who at the games in honor of Anchises defeated in a boxing contest the youthful champion Dares, who was almost killed in the struggle.

Entel'lus Monkey, or **Honuman** (*Semnopithecus Entellus*), a species of East Indian monkey, having long limbs and a very long and powerful but not prehensile tail.

Entellus Monkey.

It is regarded as sacred by the Hindoos, who dedicate temples to it, and erect hospitals for it when sick or wounded. It exhibits a familiarity bordering on impudence, and often plunders gardens with impunity, as the Hindoos consider it an honor to be robbed by it. They believe that it is a metamorphosed prince, and to kill it is considered a deadly sin; and hence these monkeys absolutely swarm in many places, especially in the vicinity of the temples.

Enteral'gia [from the Gr. ἔντερον, the "intestine," and ἄλγος, "pain"], a name given in some medical works to colic, especially of the form attended by spasmodic contractions in the muscular coat of the intestine. This intensely painful form of disease is often chronic in character, though the individual attacks are usually short—a character in which it differs from spasms of the stomach, which are often long continued. The disease is best relieved by hot applications and by the cautious use of chloroform. The tendency of late writers is to limit the use of the term *enteralgia* to cases of NEURALGIA (which see) of the intestines.

Enteri'tis [from the Gr. ἔντερον, "bowel," "intestine," and the termination *-itis*, denoting, in modern medical nomenclature, "inflammation"], an inflammation of the small intestines. The term is somewhat vaguely used by medical writers. Active inflammation of the bowels, in adults at least, is very frequently confined, for the most part, to the peritoneal coat, and the disease is hence called peritonitis. When the mucous coat of the bowels alone is actively involved, it is frequently a fatal disease in children, but in adults, with care, the majority of cases recover. Catarrhal enteritis is benefited, and generally cured, by gentle purgation. But in active disease of this kind cathartics will often greatly aggravate the evil. Such cases are best treated by rest, opiates, poultices to the abdomen, and bland nourishment. "Typhlo-enteritis" or inflammation of the cæcum, when caused by abscess or perforation of the appendix cæci, is not unfrequently fatal; when otherwise caused, recovery is to be looked for.

En'terprise, a post-village, capital of Volusia co., Fla., 12 miles below the head of steamboat navigation on St. John's River (although steamers have ascended sixty miles higher), 80 miles S. of St. Augustine. It is a place of winter resort, and the head-quarters of sportsmen (both for fishing and gunning) in this part of Florida. Here is the "Green Spring," a remarkable sulphur spring 80 feet in diameter and 100 feet deep. Enterprise has a courthouse and good hotels.

Enterprise, a post-village, capital of Clark co., Miss., has two weekly newspapers.

Enterprise, a township of Linn co., Mo. Pop. 322.

Enterprise, a village of Lanier township, Preble co., O. Pop. 61.

Enthu'siasm [Gr. ἐνθουσιασμός, "inspiration," from ἐν, "within," and θεός, a "god"] refers to the emotions; inspiration to the imagination; revelation to the intellect. An idea may burst upon a man as a revelation; he throws it upon the world as an inspiration; it belongs to the world to receive it with enthusiasm. Enthusiasm is merely passive, a merely receptive state of mind; and it is important, both in religion and æsthetics, to be fully aware of this being its true character, for in religion it causes pitiful misery when every upheaval of our feelings is mistaken for a divine revelation—the more so as enthusiasm, in accordance with its merely passive nature, is as ready to run after a foolish whim as it is to follow the exalted wisdom. And in æsthetics nine-tenths of that disagreeable stuff with which modern literatures are loaded under the names of poems, novels, tales, etc. would never have been read, perhaps even not written, if people had understood thoroughly that art depends for its production wholly on inspiration, whilst enthusiasm only makes us fit for the enjoyment of its gifts.

En'thymeme [from the Gr. ἐν, "in," and θυμός, "mind"], in logic, a syllogism of which one of the three parts (generally the major premise) is suppressed or held in mind—*e. g.* "The freedmen ought not to vote, because they cannot read." According to De Quincey (*Historical Essays*, vol. ii., p. 215 seq.), the Aristotelian enthymeme is an argument in respect to matters probable rather than demonstrable. (So also THOMSON, "Laws of Thought," p. 284.) Aristotle's own definition for the rhetorical enthymeme is, "a syllogism from probable propositions or from signs." By *probable propositions* he means those which are general, but not at all universal, as "Injured men seek revenge." By *signs* he designates facts or marks, such as attend upon other facts or conceptions, so that from the presence of the sign we suspect or know that the thing signified is also present. The rhetorical enthymeme, when based on signs, is always affirmative, taking no account of negative indications. Its results are universal, and may amount to practical or even formal demonstration.

Entomology is the department of zoology which treats of Insects. It includes the study of their form, structure, development, habits, names, classification, and geographical distribution; and also the examination of the relations which Insects sustain to other animals and to Man. The name of the science is derived from two Greek words—ἔντομον, *entomon*, an "insect," and λόγος, *logos*, a "discourse."

In general terms it may be stated that the science of Entomology dates from the time of Aristotle; for this accurate observer and learned scholar, whose writings on Natural History are the more admired the more they are studied, considered insects also, as well as other animals, scientifically, pointing out the limits of this interesting group of animals, and subdividing them into minor groups, with a wonderful degree of accuracy. From the time of Aristotle for a period of about 1800 years, little or nothing was done, so far as we know, in the science of Entomology. After this long period of inactivity in this science, Conrad Gesner, a poor Swiss, born in 1516, became a physician at Zurich, and, in addition to his other duties, gave much time to natural history subjects, collecting all that was then known of the natural history of animals in general, and writing special papers on Insects, which were published after his death, by Thomas Mouffet, an English physician and naturalist, who died about the year 1600, and whose entomological writings were published in one folio volume, illustrated with 500 wood-cuts, in London, in 1634.

From the times of Gesner and Mouffet the science of Entomology has always had many votaries—so many that the whole space allotted to this article would not contain even a list of their names and the titles of the books and papers which they have published on this interesting and important subject. Nay, it requires two octavo volumes to enumerate the writers on Entomology and to give the full titles, and dates, and places of their publications, as may be seen by examining Dr. Hagen's valuable work, "Bibliotheca Entomologica," 2 vols. 8vo, Leipsic, 1862–63. And it should be added here, that since the publication of that work new writers have come forward, so that several scores of writers and hundreds of papers must be added to the lists enumerated in Dr. Hagen's volumes of ten years ago.

But while no complete list even of the names of the writers on Entomology can here be given, we must not fail to mention a few such names as Redi, Goedart, Malpighi, Swammerdam, Lyster, Madame Merian, Leuwenhoeck, Vallisnieri, Ray, Réaumur, Linnæus, Charles de Geer, Roesel de Rosenhof, Bonnet, Clerck, Lyonnet, Sepp, Geoffroy, Schaeffer, Brunnich, Pallas, Drury, Cramer, Fabricius, Esper, Stoll, Moses Harris, Schrank, Schiefermüller, Villiers, Thunburg, Rossi, Olivier, Smith and Abbot, Pierre André Latreille the "Prince of Entomologists," Panzer, Herbst, Sturm, Illiger, Marsham, Kirby and Spence, Palisot de Beauvois, Prykul, Meigen, Jurine, Savigny, the Hubers (father and son), Schoenherr, Treviranus, Wiedman, Ramdohr, Gyllenhal, Ochsenheimer, Hubner, Fallen, Herold, Klug, Gravenhorst, Meckel, Marcel de Serres, Leach, Suckow, Walckenaer, Macleay, Carl Ernst von Baer, Straus-Durckheim, Lepelletier de St. Fargeau, Dalman, Waldheim, Dumeril, Dufour, Duponchel, Curtis, Stephens, Stainton, Swainson, Wood, Horsfield, Gebler, Germar, Étienne Geoffroy Saint-Hilaire, Eschscholtz, Godart, Benelli, Carus, Mannerheim, Guérin Méneville, Rathke, Macquart, Audouin, Zetterstedt, Milne-Edwards, Boisduval, Rennie, Spinola, Kolliker, Leuckart, Brullé, Gené, Guénée, Pictet, Rambur, Kollar, Dahlbom, Say, Van der Hoeven, Zaddach, Lucas, Dejean, Wagner, De Castelnau, Griffith, Lacordaire, Audinet-Serville, G. R. Gray, White, Walker, Dallas, Smith, Doubleday, Cuvier, Burmeister, Shuckard, Westwood, Erichson, Dujardin, Herrich-Schaeffer, Newport, Blanchard, Longchamps, Bowerbank, Le Conte, Haldeman, Harris, Siebold, Gegenbaur, Rondani, Murray, Lucaze-Duthiers, Agassiz, Hagen, Melsheimer, Giebel, Berendt, Uhler, Fitch, Loew, Duval and Migneaux, Wollaston, Osten-Sacken, Langstroth, Huxley, Wallace, Leidy, Packard, Scudder, Grote, Norton, Edwards, Trimble, Claparède, Gerstaecker, Lubbock, MacLachlan, Walsh, Thorell, etc., etc.

The vast numbers of insects, their varied forms, beautiful and in many cases splendid colors, wonderful transformations, and their not less wonderful instincts and habits, and the intimate and important relations which they sustain to other animals and to Man, combine to render the science of Entomology exceedingly fascinating and highly important, and worthy the attention it has received and is still receiving from the ablest minds.

The science of Entomology is of the highest importance, when considered merely from the so-called practical point of view; for it teaches what kinds of insects are beneficial to man, and what kinds are injurious, and thus it shows him which to preserve and which to destroy. It makes him acquainted with the habits of insects, and thus enables him the better to preserve those that are beneficial, and to meet and resist the ravages of those that are injurious to the crops of the field, orchard, and garden, and of those which are injurious to the food and clothing in the store-rooms and closets.

The important relations, however, which insects hold to Man, and the corresponding importance of Entomology, are but little understood except by those who have given some attention to these animals and to this fascinating and exceedingly important science. The masses of men little realize the fact that some kinds of insects destroy millions of dollars' worth of property annually in every country, and that other kinds furnish the world with many of the comforts and even with the luxuries of civilized life—with silks, satins, and velvets, and with dyes whose fame is as old as history and as wide as the civilized world, and even with every drop of black ink which flows from the pen of the schoolboy, accountant, philosopher, and poet.

The position which Insects hold in the Animal Kingdom may be readily seen by the following classification:

Vertebrates	Mammals, Birds, Reptiles, Batrachians, Fishes.
Articulates	Insects, Crustaceans, Worms.
Mollusks	Cephalopods, Gasteropods, Acephals, Brachiopods, Tunicates, Polyzoans or Bryozoans.
Radiates	Echinoderms, Acalephs, Polyps.
Protozoans	Infusoria, Porifera, Rhizopoda.

It is thus seen that Insects are the highest class of the Articulates; and it is this class with which the science of Entomology exclusively deals. And this class is now to be defined and classified, so far as our limits permit.

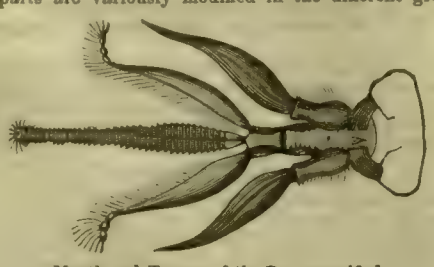
Insects are animals whose bodies are divided transversely into rings or joints more or less movable upon one another, and whose hard parts are upon the outside, and whose respiratory apparatus consists of air-holes, called stigmata, placed along the side of the body, and which open into a system of air-tubes which branch throughout the interior of the body, and thus carry air into every part. These air-tubes each consist of two membranes enclosing between them a spirally coiled fibre, thereby having great strength and flexibility. As in all other articulated animals, their alimentary canal occupies the central line of the body, and above it is the dorsal vessel or so-called heart: and their nervous system consists of a sort of brain lying above the œsophagus, from which two threads, passing around and below the œsophagus, extend beneath the alimentary canal along the floor of the general cavity of the body, and connect at certain distances small nervous centres or ganglia, whence arise the nerves of the body and limbs.

The class of Insects is by far the largest in the Animal Kingdom. It is regarded as much larger than all other classes combined. About 200,000 species of insects are already known, and the whole number may be safely estimated as high as 500,000 species. The species are mostly small—many are microscopic in size—but some kinds in the warm regions are several inches, even a foot, in length. The average length, however, is probably much less than one inch. This vast class may be divided into three groups, which Leuckart and many others regard as orders:

Insecta, or Insects.
- I. Hexapoda, or Insects proper, as Bees, Butterflies, Flies, Beetles, Bugs, Grasshoppers and Dragon-flies.
- II. Arachnida, as Spiders and Scorpions.
- III. Myriapoda, as "Galley-worms," Centipedes, etc.

Dr. A. S. Packard, Jr., in his valuable work entitled "A Guide to the Study of Insects," gives the following tabular view of the Classification of Insects, which we gladly insert here, as valuable both to the entomological student and to the general reader:

The Class of Insects.



Order I.—Segments grouped into three distinct regions; eyes compound and simple; two pairs of wings (some kinds are wingless, and some, as the Diptera, have only one pair); six thoracic legs; one pair of jointed abdominal appendages. A more or less complete metamorphosis.	Hexapoda, or Six-footed Insects.

Order II.—Segments grouped into two regions, a false cephalothorax (the so-called cephalothorax of Spiders is not like that region in Crabs, the head being much freer from the thorax), and an abdomen; no antennæ; eyes simple; wingless; four pairs of thoracic legs; three pairs of jointed abdominal appendages (spinnerets) often present. No metamorphosis.	ARACHNIDA, or SPIDERS.
Order III.—Body cylindrical and worm-like. Segments not grouped into regions (except in the recently hatched young). Head free; eyes simple; antennæ present; wingless; yolk-sac present for a short period after hatching. No metamorphosis.	MYRIAPODA, or CENTIPEDES.

These three groups or orders may now be briefly noticed.

HEXAPODA.—The first order, Insects proper, is composed of insects which have their body divided into three plainly marked regions—the head, thorax, and hind-body or abdomen. The head is furnished with mouth, eyes and antennæ; to the thorax are appended the legs and wings; and the abdomen contains the principal organs of digestion, and other viscera, and to it also belong the piercer and sting with which many kinds of insects are provided. The Insects proper have only six legs—and hence are often called Hexapod Insects—and these are attached to the under side of the thorax, one pair to each of the three rings of which the thorax is composed. The leg consists of the hip-joint, by which it is fastened to the body, the thigh, the shank, and the foot, the last consisting generally of five pieces placed end to end and called tarsi, and generally armed at the end with one or two claws. The wings are normally four, but in some, as in Flies, etc., there are only two, and in others, as in Fleas, etc., these organs are wholly wanting. The wings of insects are at first little, soft, sac-like bodies containing tracheæ. They grow from the side of the thorax of the pupa at points above the insertion of the legs. During the pupa stage they are pad-like, but when the pupa-skin is shed, they rapidly expand with air and become broad and delicate wings. The wings of insects are thus simple expansions of the general covering of the body spread over a network of horn-like tubes. These tubes, it may be remarked here, are found to be double, consisting of a central air-tube enclosed within a larger tube filled with blood; and hence the aëration of the blood is also carried on in the wings, and thus these organs serve both the purpose of lungs and of flight. And it may be further remarked here that the number and position of these veins are of very great importance to the entomologist in classifying the genera and species of insects. The typical number of primary veins is five. They diverge from the base of the wing, and divide into veinlets, from which cross-veins arise, all together forming a network of veins and veinlets. The five main veins are, beginning at the front edge, the costal, the sub-costal, the median, the sub-median, and internal. Sometimes the median divides into four. The front or costal vein is undivided; the sub-costal and median are divided into several branches; the submedian and internal are generally simple. The piercer mentioned above is properly an ovipositor, and is in some cases a jointed tube, and is used for conducting eggs into holes where they are to be left to be hatched; in other cases it is a scabbard containing a central borer, or saws in some cases, which are used in making holes in which eggs are to be deposited. The sting with which many insects, as bees and wasps, are provided, is merely a modified ovipositor, and consists of a sheath covering a sharp instrument for inflicting wounds, and connecting with it inside of the body is a sac of poison.

The digestive system of insects is quite complicated, and its parts are variously modified in the different groups

Mouth and Tongue of the Bee, magnified.

of these animals. In some kinds the mouth parts are modified for biting and chewing purposes; in others they are so modified as to be adapted for sucking organs. The parts called mandibles are organs situated on each side of the mouth-opening, and they vary greatly in form and size. They usually consist of a single joint; and this joint or part is often subdivided into three parts, each ending in a sort of tooth for the purpose of cutting food. The cutting edges are opposed to each other, or overlap, and their motion is horizontal or side-wise, instead of vertical as in the motion of the jaws of vertebrated animals.

The parts called maxillæ are much more complicated organs than the mandibles, and are inserted on the under side of the head, and just behind the mouth. Their function is to seize food and retain it within the mouth, and to aid the mandibles in comminuting it. Each maxilla consists of a basal joint, beyond which it is divided into three lobes—namely, the footstalk, the palpus-bearer, and the blade. The maxillary palpi are slender-jointed organs, very flexible and sensitive. Insects have a pharynx, a gullet, a first stomach or crop, a second stomach or gizzard, a small intestine, a cæcum, etc.

The circulatory system is imperfect, as it exists only in a rudimentary form. Just under the covering of the back there is a long tube which is called the heart, and this organ performs regular alternate movements of contraction and dilatation. The blood enters this tubular organ by openings along its sides, the openings being furnished with valves which prevent its return, and the blood escapes at the foremost end as the organ contracts, and thus the blood is kept in motion throughout the interior of the animal, and thus the waste of the body is supplied and growth secured. The blood of Insects is colorless, and, as already indicated, is not contained in arteries and veins as in the higher animals, but it fills all the interior of the animal not occupied by internal organs, and it permeates the tissues of the organs themselves.

As already indicated, the respiratory system is very different from that of the higher animals. On the sides of the body are generally breathing-holes or stigmata, nine on each side, and these open into air-tubes called tracheæ, which branch throughout the body, carrying air into every part, and thus aërating the blood in the most perfect manner, and thereby fitting these animals for rapid and long-continued motion.

The muscular system of Insects is beneath but continuous with the integument, and it corresponds to the jointed structure of these animals. It consists of straight fibres, more or less isolated, and not gathered into bundles as in the vertebrates, although they are in many cases striated, as in the latter branch. The muscles are colorless, or transparent, or yellowish-white, and very soft. The muscular system is found to be the simplest in the lowest insects, and in the larvæ of all forms; and it is more complex in the head than elsewhere, and more complex in the thorax than in the abdomen. The muscles in Insects are exceedingly numerous. Lyonnet found 3993 muscles in a single larva (*Cossus ligniperda*), 228 of these being in the head. The muscular power of Insects is perfectly enormous. It is stated on good authority that the flea can leap 200 times its own height, that beetles have been known to gnaw through lead pipes, and that the European Stag-beetle (*Lucanus cervus*) has gnawed a hole an inch in diameter through the side of an iron canister in which it was confined!

The organs of sight in Insects consist of ocelli and eyes. Theoretically, the ocelli are the most anterior organs of the head, but in the process of development they are carried backward, so that in the adult insect they appear on top of the head. The ocellus is the simplest form of the eye. The ocellus consists of a "very convex, smooth, single cornea, beneath which is a spherical crystalline lens, resting upon the plano-convex surface of the expanded vitreous humor, the analogue of the transparent cones of the compound eyes." The ocelli constitute the only visual organs of most of the Myriapod, of all of the Arachnid, and of the larvæ of many of the Hexapod Insects. The number of ocelli in adult insects is generally three. These organs are generally present except in the large majority of Beetles. The real eyes of Insects are compound, and are made up of a congeries of simple eyes. During the development or growth of the

Head and Eyes of the Bee, magnified.

insect the simple eyes of the larvæ increase in number, and at length coalesce to form the compound eye. The number of facets or cornea in the compound eye is very great in some kinds of insects, 3650 having been counted in the eye of a butterfly. The form of the facets is generally hexagonal, but in some species it is quadrangular.

As to the organs of hearing, smell, taste, and touch, but little is positively known. The antennæ seem to serve the purpose of feelers, and it is believed that they are also connected with the sense of hearing. But it should be remarked here that Siebold found an auditory apparatus in the fore legs of some species of grasshoppers.

Their nervous system, as already stated, consists of a double series of nervous ganglions or knots of nervous matter connected by a double cord of nervous threads; and these are situated along the ventral side of the animal, connected, however, with a nervous centre in the head. From these ganglia arise the nerves of the body and limbs.

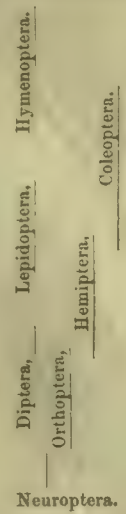
It is hardly necessary to say that insects are never spontaneously generated, as some persons suppose, but they are produced from eggs, which are hatched after they are laid in some favorable place; or, in some cases, they are hatched in the body of the parent insect, and then brought forth as moving forms.

The Luna Moth (*Tropæa luna*): 1, Imago; 2, Pupa or Chrysalis; 3, Larva.

In passing from the egg state to the adult state, Insects undergo great changes of form and habit. These changes are called transformations or metamorphoses, and they are so great in most cases that the same insect at different ages may easily be mistaken, by one not an entomologist, for as many different animals. There are at least three more or less distinctly marked stages in the life of every insect after it leaves the egg—viz., the *larva*, the *pupa* or *chrysalis*, and the *imago* state.

In the larva state Insects are more or less worm-like, and consist of thirteen or fourteen apparent segments, besides the head; and they pass most of their time in eating, and as a consequence of this they grow very rapidly. When the larva of an insect has attained its full growth as a larva, it retires to some suitable place, and in many cases it spins a silken covering called a cocoon, then sheds its skin, and appears as a much shortened, oblong, oval, or conical body, apparently lifeless; in this form it is called a *pupa* or *chrysalis*. In a majority of species, however, no silken covering or cocoon is made, but the pupa itself is essentially of the same form as those found enclosed in a cocoon. At the end of the pupa state, which varies greatly in duration in the different species, the insect sheds its pupa-skin and comes forth fully grown, and in most species provided with wings; and in this state it is called a perfect insect or *imago*. After insects enter upon the adult or imago state they do not increase in size. They now provide for a continuation of their species, and then, in most cases, soon perish. All insects which pass through the changes described above are said to undergo a complete transformation. This word "transformation" does not, however, convey the exact idea of the changes, for the changes are those resulting merely from growth and development, and not from true transformations. In a word, the animal is one and the same during all its various forms.

But there are some kinds of insects which do not apparently pass through all the changes enumerated above, but whose larvæ pass by insensible gradations to the pupa state, and from the latter to the perfect insects, all the while remaining in a state of activity. These are said to undergo only a partial transformation. The grasshopper, for example, is hatched from the egg as a wingless insect. It eats voraciously, grows rapidly, hops about without the use of wings, sheds its skin more or less regularly, and appears after each shedding with longer wings and more completely developed limbs, until at length it ceases to grow, and then, shedding the skin for the last time, comes forth an imago or adult grasshopper. The larvæ of those insects which undergo only a partial transformation have only six legs, the same as adult insects. But of the larvæ which undergo a complete transformation, some kinds, as maggots, have no legs; others have a pair of legs to each of the three first segments; others have a pair to each of the three first segments, and, besides these, several fleshy legs, ten or more, placed beneath the abdominal segments, and known as prop-legs.



Insects proper have been variously classified, and different ranks have been assigned to the groups into which they have been divided. According to Packard and others, Insects proper may be divided into seven groups (first proposed by Linnæus) or sub-orders, thus:

1. *Hymenoptera*, as Bees, Wasps, Ichneumons, Ants, Saw-flies, etc.
2. *Lepidoptera*, as Butterflies and Moths.
3. *Diptera*, as Flies, Mosquitoes, etc.
4. *Coleoptera*, as Beetles.
5. *Hemiptera*, as Bugs, Cicadas, Plant-lice, etc.
6. *Orthoptera*, as Grasshoppers, Crickets, etc.
7. *Neuroptera*, as Dragon-flies, May-flies, Ant-lions, etc.

Dr. A. S. Packard, Jr., recognizes two series in these seven sub-orders—a higher and a lower—and arranges them thus:

First and Higher Series.—Body usually cylindrical; prothorax small; mouth-parts more generally haustellate (formed for sucking); metamorphosis complete; pupa inactive; larva usually cylindrical, very unlike the adult.	1. Hymenoptera. 2. Lepidoptera. 3. Diptera.
Second and Lower Series.—Body usually flattened; prothorax large and squarish; mouth-parts usually adapted for biting; metamorphosis incomplete; pupa often inactive; larva flattened, often resembling the adult.	4. Coleoptera. 5. Hemiptera. 6. Orthoptera. 7. Neuroptera.

In order to show, in a general way, the relative rank of the seven sub-orders and of two series of Six-footed Insects, Dr. A. S. Packard gives the following diagram:

It must be here stated that many naturalists regard these groups as real orders instead of sub-orders; and they stand as orders in many books which the student and reader may have occasion to consult on this subject.

A brief notice of each of these groups may now be given, with such illustrations as will give the general reader a clear idea of some of the characteristic forms in each group.

Hymenoptera.—The Hymenoptera (ὑμήν, *hymen*, a "membrane;" πτερόν, *pteron*, a "wing") have four membranous wings, the hind pair the smaller, and all traversed by a comparatively few veins. These insects have four jaws, the upper pair fitted for biting, and the lower pair the longer and softer, and with the lower lip in many cases adapted for collecting honey. The females are provided with stings, but the males have no weapons excepting their jaws. In passing from the egg state to the imago state they undergo a complete transformation. All of the Hymenopters are diurnal in their habits, and they fly swiftly. They are regarded by Dana as exhibiting the normal size of the Insect type. Of all the Hymenoptera, the Bees are of the greatest popular interest, even if we may not say that they are of the greatest scientific interest; and a volume might well be devoted to their intensely interesting and fascinating history. Thanks to Réaumur, the Hubers, and others, we have volumes of interesting and reliable information in regard to the Hive-Bee (*Apis*), the most wonderful representative of this group.

In general, Bees are eminently social in their habits, and the species are composed of three sorts of individuals—*females* or *queens*, *males* or *drones*, and *imperfectly developed females* or *workers*: the last are smaller than the others, and are often improperly called *neuters*. In a single community of the Hive-bee (*Apis mellifica*) there are sometimes 50,000 workers, 2000 males, but only one adult queen. This species has now been introduced in all countries of the civilized world. The celebrated Italian bee is regarded as one of its varieties. The Hive-bee has engaged the attention of the best observers for more than one hundred and fifty years, and many interesting and wonderful things have been found out regarding its structure and habits; but much still remains to be studied in connection with this wonderful insect.

As regards the workers, they are believed to be of two kinds—the nurses, whose function is to build the cells, collect honey, and feed the larvæ; and the wax-makers, which, from the food they eat, secrete wax beneath their ventral segments, from which it is taken in thin scales. The bee cells are theoretically hexagons with pyramidal bases, and the greater angles are given as 109° 28′, and the lesser as 70° 34′. I say that the cells are hexagons, theoretically, because it has been shown by Prof. Jeffries Wyman (*Proc. Am. Acad. of Arts and Sci.*, vol. vii., 1866) that the cells are all more or less imperfect when considered mathematically. And it may be added here that it is still an open question as to the exact way in which the form of the cell is secured or brought out. Some naturalists regard the cell as the result of the labor of the bee directed by mere instinct; others believe the bee to be directed in the work by a sort of reason; and others, still, believe that the form of the cell is a necessary resultant of the labor of bees working together.

The cells are of sizes in accordance with the three sizes—queens, drones, and workers—of bees to be produced. The ordinary cells are arranged horizontally—that is, the comb is made to assume a vertical position; but the queen cells, where the queens are reared, are in a vertical position, mouth downward, and are somewhat pear-shaped, and vastly larger than ordinary cells. The bottoms of the cells of the two tiers do not come directly opposite each other, cell to cell, but the bottom of each cell forms a portion of the bottom of each of three opposite cells, and thus the strength of the cells is greatly increased. The diameter of the cells for the larvæ of the workers is two and two-fifths lines; for the larvæ of the males, three and one-third lines; and the male cells are generally in the middle of the combs.

The bee-larvæ are fed with bee-bread, after it has been worked over in the stomach of the bee; this bread is composed of the pollen of flowers. When bees lose a queen they select an ordinary larva, and by giving it more room and better food they cause it to develop into a queen bee. When the larvæ are ready to go into the pupa state the foster-parents close up the cells with a lid of wax, convex on the drone-cells, and nearly flat on the worker-cells; then the larvæ spin their cocoon. The queen is about sixteen days in coming to maturity; workers twenty days, and drones twenty-four days. The queen sometimes lays 2000 to 3000 eggs in a day, and during her lifetime—perhaps five years—she lays more than a million of eggs. The laying of worker eggs begins in January and February; after this, in the spring, male eggs are laid.

Bees gather the nectar or honey of flowers, pollen, and resinous wax or propolis. When covered with pollen they collect every particle and knead it into little masses, one of which is placed on each hind leg, and in this way it is carried home to the hive. They get the resinous wax or propolis from resinous leaf-buds and leaves, and they use it in finishing the combs and in stopping crevices, etc.

But our space will not allow us to describe these insects at length, and so we may take our leave of them by enumerating here a few of their instincts and habits mentioned above, together with a few others not less wonderful than these. We may here say, then, that when about to swarm Hive-bees send out scouts; they follow their queen; they carefully cleanse their selected abode; they stop all crevices with propolis; they ventilate the hive by the rapid movements of their wings; they guard the entrance; they keep equal spaces between their combs in the hive; they solder the angles of cells and polish the interior; they produce a yellow tinge to the comb, as is believed, by a sort of varnishing; they extract honey from flowers; they collect pollen, and, as is believed, only from one species of flower on a given excursion; they hasten home on the approach of rain; they find their way back after the most extended wanderings; they feed their companions on their return to the hive; they store away the surplus pollen; they swallow pollen and change it into fit food for the larvæ; they feed the larvæ with the right sort of food; they cover the grub-cells with a waxen lid, convex or concave according as the grub is a drone or a worker; they cleanse the cells after the young bees leave them; they retain the young queens in the cells till they are wanted, and they feed them while thus kept confined; they release the queens in the order of their age, the oldest being released first; they cause the queens to fight, and they devotedly follow the survivors, and if they lose their queen they immediately go to work to raise another by giving extra food and room to an ordinary larva or grub; they kill the drones, and drag them from the hive when they are not wanted; and finally, they all have their appropriate parts to perform, and they perform these parts with unerring regularity and in the most perfect manner.

The Humble-Bees (*Bombus*) are in general of large size, and have exceedingly hirsute bodies. They build their nests in or on the ground, and their cells are large, oval, and more or less separate, and their communities are much smaller than those of the hive-bee, but there are in some

cases several hundreds of humble-bees in a single community, and each community arises from a single female which has survived the storms of winter; for the community, as a community, does not survive the winter.

The Wasps (Vespidæ) are other representatives of the Hymenoptera, and like the Bees many species live in colonies composed of females, males, and workers. They construct complex nests under ground or attached to overhanging rocks, to trees, fences, or buildings. These nests consist of tiers of hexagonal cells with their mouths downward, and supported by pedicels; and the cells in a single nest, in some cases, number 16,000. These representatives of the Hymenoptera are especially interesting as being the first paper-makers. Their nests are made of a paper-like substance, which is merely wood reduced to a paste by the action of the jaws of these insects, and this, put into the required form, is left to dry—essentially the same thing that our paper-manufacturers are doing by other processes and on a large scale in their mills to-day. The Wasp communities, like those of the Humble Bees, are dissolved on the approach of winter; and each female that survives the winter founds a new colony the ensuing spring. Some kinds of wasps, however, are solitary in their habits.

The Ants (Formicidæ) are other members of the Hymenoptera which live in communities composed of females, males, and workers; the two former are furnished with loosely attached wings, and the last are destitute of wings. The workers have the care of the nest and of the rearing of the young; they go in search of food, feed the larvæ, take them into the sunshine in fine weather, and back again into the nest at night or when bad weather comes, and they watch over them with a wonderful fidelity. Most ant-hill communities are composed of individuals of one and the same species; but in some cases the workers procure auxiliaries by visiting the ant-hills of other species, and forcibly taking the larvæ and pupæ and bringing them to their own nest, and there having them reared and trained to work for the community in which they are reared!

The Ichneumons (Ichneumonidæ) are members of the Hymenoptera which are interesting not only on account of their structure, but because of the fact that they are very destructive to other insects, especially to those, as the Lepidoptera, which in the larva state are injurious to vegetation. They are therefore very useful insects. Ichneumons deposit their eggs on the eggs, larvæ, and pupæ of other insects, and upon these the larva-ichneumon feeds when hatched. These insects have the body long and narrow, the antennæ long, the ovipositor generally long and protected by two thread-like organs of the same length as

Ichneumon.

the ovipositor itself. The color of the Ichneumon is generally black, varied with red, yellow, or white. Some species, however, are wholly reddish.

Of all the Hymenoptera none are more interesting, considered from one point of view, than the Gall flies (Cynipidæ), since these small insects, by puncturing a species of oak growing in Western Asia, produce the nut-galls of commerce, and these supply the world with ink. The Gall-flies have the head short and broad, the thorax thick and oval, and the abdomen much compressed and attached to the thorax by a very short peduncle. They are very numerous, and the different kinds attack different kinds of plants. Some species attack the Oak, others the Rose, etc. The females have a long ovipositor, with which they insert their eggs into leaves and other parts of plants, and these punctures cause galls; and the form and nature of the gall depends both upon the kind of gall-fly and upon the kind and part of the plant punctured.

Among the largest of the Hymenoptera are those Boring Saw-flies known as "Horntails," which have the body long, nearly cylindrical, and the blunt abdomen ending in a horny point. Beneath this abdomen they have a long saw-like and powerful borer, with which they bore holes into trees, in which they deposit their eggs: and it may be added that their larvæ are among the great host of tree-borers.

There are other saw-flies belonging to the Hymenoptera, but they belong to a separate family—namely, to the Tenthredinidæ. These Saw flies are of various species, some of which attack the Rose, others the Vine, others the Elm, etc. All have an ovipositor consisting of double saws, lodged under the body and covered by two pieces as a sheath. They are sluggish in their habits. Their larvæ have from eighteen to twenty-two legs, and are found in communities on the leaves of birch and alder, holding fast by their true legs, while the rest of the body is curved upward. Other species, however, appear like slugs on the leaves of the rose and of fruit trees. The larva of the Elm Saw-fly is large, and covered with a thick skin with numerous transverse wrinkles, and when at rest it is coiled so as to somewhat resemble a snail-shell.

LEPIDOPTERA.—The second group of Insects proper—namely, the Lepidoptera (λεπις, *lepis*, a "scale;" πτερόν, *pteron*, a "wing")—is composed of insects which have

The Peacock Butterfly, *Vanessa Io*.

four wings covered with scales that are easily removed. The Lepidoptera have a tongue consisting of two grooved threads placed side by side, so that the grooved sides come together and form a channel by their junction, and thus the tongue is adapted for sucking purposes; and accordingly these insects drink the dew and feed upon the honey of flowers. When not in use this tongue is rolled up like a watch-spring beneath the head, and more or less concealed on each side by an organ called a palpus. The legs of the Lepidopters are six in number, but the forward pair is short, and sometimes rudimentary, or wanting. In the larva state these insects are called caterpillars, and they have from ten to sixteen legs. Most kinds of caterpillars feed upon plants. Some kinds eat the leaves, others the blossoms, others the seeds, others the stems, and others the roots. Other kinds, however, eat fabrics, furs, feathers, leather, meat, lard, and even wax. In coming to their full growth as larvæ they usually change their skins four times.

The Lepidopters include the Butterflies and the Moths. The former are readily distinguished by their knobbed antennæ, and by the fact that they hold their wings erect when they alight. The Moths have variously formed, but never knobbed, antennæ, and their wings are sloping when they alight. All of the Lepidopters pass through a complete transformation in coming to maturity. Many of the caterpillars of the Moths spin cocoons; many, however, do not, and none of the caterpillars of the Butterflies spin cocoons.

The Butterflies of North America are numerous, and many of them are exceedingly beautiful, as any one may see by examining them, or the splendidly illustrated works of Edwards, and those of Scudder, as well as the illustrations of our butterflies in foreign works.

Of the Moths we have room only to mention the Sphinges or Hawk Moths, and a few of the broad-winged moths. The Hawk Moths (Sphingidæ) are mostly very large lepidopters, and the wings are long and comparatively narrow. These moths fly with great rapidity, and with few excep-

tions they visit the flowers to secure honey in the morning and evening twilight; and as they balance themselves before the petunias and other flowers, by the rapid movements of their wings, they may easily be mistaken for humming-birds. Their tongue is exceedingly long—in some cases five or six inches. The caterpillars of these moths are very large, and they assume curious attitudes. Supporting themselves on their hind legs, they elevate the forward part of the body, and remain for hours in this sphinx-like position.

Some of the broad-winged or Silkworm Moths (Bombycidæ), as *Cecropia*, *Polyphemus*, *Luna*, etc., are remarkable for their large size; others, as the beautiful *Deiopeia* and the Wood-Nymphs (*Eudryas*), are remarkable for their beauty; and all in the larva state spin silken cocoons, in

Silkworm, Moth, Larva, and Chrysalis.

which they pass into the pupa state. One of the most common of the small broad-winged moths, is the Tent-caterpillar Moth, which in the larva state lives upon neglected apple trees, and upon wild-cherry trees, and spins the well-known tent-like nests.

Diptera. — The Diptera (δίς, *dis*, "double;" πτερόν, *pteron*, a "wing") are so named from the fact that they have only two real wings, the place of the hind wings being occupied by two knobbed threads called poisers or balancers. Their mouth is modified for either sucking or lapping. The sucker or proboscis is composed of two to six bristle-like organs, in some cases as sharp as are the sharpest needles, and either enclosed in the grove of a sheath terminated by two lips, or covered by one or two laminæ which serve the purpose of a sheath. They undergo a complete transformation in coming to maturity. Their larvæ are without feet, and are called maggots. The pupæ are in most cases enclosed in the dried skin of the larvæ. Some kinds of dipters, as Mosquitoes, lay their eggs in the water, and their larvæ may be seen in summer in all stagnant pools, where they are popularly known as "wrigglers." They rest with their head downward, and the hind extremity, which contains the respiratory organs, is at such times at the surface of the water. They are very active, and move with a wriggling motion through the water, but come to the surface from time to time to secure air through their respiratory organs. At the end of their larval state they shed their skin, but still remain in the water, and move by means of their hind-body; but now they assume a different attitude, and the respiration is carried on through two tubes situated on the thorax. At the end of the pupa state, which lasts only a few days, the skin splits upon the back, between the breathing-tubes, and the winged insect or imago appears, and after resting a while on its empty pupa-case as it floats upon the water, it flies away in search of a victim whom it may pierce for blood. These kinds of dipters discharge a poisonous fluid into the wounds which they inflict, and this is the cause of the irritation which follows their attacks.

Some species of the Diptera, as the Hessian Fly (*Cecidomyia destructor*, Say) and the Wheat-fly (*Cecidomyia tritici*, Kirby), are very injurious to the farmer, sometimes destroying whole wheat-fields. The Hessian Fly received its name from the popular belief that it was brought to this country, in straw, by the Hessian troops. It is very small, only about one-tenth of an inch in length. The females lay their eggs on the young blades of wheat, and the eggs hatch in about four days, producing pale red maggots. The larvæ crawl down the leaf, and get between the latter and the main stalk near the joint, and here they injure and often destroy the plant by sucking the sap. The Wheat-fly, on the contrary, lays its eggs in the opening flowers of the wheat, also in those of rye, barley, and oats. In about eight days the eggs hatch, producing little yellow larvæ or maggots, which are found within the chaffy scales of the grain.

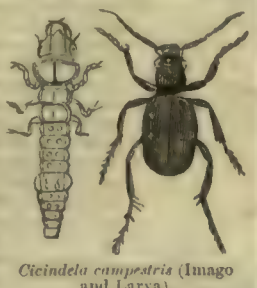
Several species of the Diptera are very injurious, or at least annoying, to cattle and horses. One of these is known as the Black Horse-fly (*Tabanus atratus*, Fabricius), another as the Orange-belted Horse-fly (*T. cinctus*, Fabr.), and another the Lined Horse-fly (*T. lineola*, Fabr.). All of these have the eyes very large, covering nearly the whole head, and they have a proboscis enclosing six sharp lancets in the female, and four in the male.

Other members of the Diptera, as the Asilus Flies (*Asilici*), are very long-bodied, and very destructive in their larva state to the roots of plants, and in the adult state they are very rapacious, seizing and destroying other insects.

Other dipters still are the Bot-flies (Œstridæ), which in the larva state inhabit various parts of the body of herbivorous animals, as horses, cattle, sheep, etc. These flies have very short antennæ, large head, and the wings cover the balancers; and the hind-body of the females has a conical tube bent under the body, and with it they lay their eggs when flying. One species lays her eggs upon the fore legs of the horse, another upon the lips, and another on the throat. By biting the parts where the eggs are laid, the horse gets them into his mouth, and swallows them. The larvæ, by means of hooks, cling to the walls of the stomach till they come to the end of their larval life. Another species (*Œstrus bovis*, Fabr.) lays her eggs on the backs of the cattle, and the larvæ penetrate the skin and live there in open sores. Another species (*Cephalomyia ovis*, Linn.) lays her eggs in the nostrils of sheep, and the larvæ crawl into the cavities of the head, and in many cases produce death.

But by far the largest group of all the Diptera is that

Flies.



which Latreille called the Muscidæ, which includes about one-third of all the members of this sub-order, and which are known under the popular names of House-flies, Flesh-flies, Blow-flies, Cheese-flies, etc. Meigen has already, a long time ago, described 1700 species of these flies as belonging to Europe, and there is probably even a greater number in this country. These flies have a wonderful power of reproduction. Some species, as the Flesh-flies, are viviparous. Réaumur found 2000 larvæ in a single specimen of this sort.

Among the Diptera there are, as in other groups, some apparently anomalous forms. One of these is seen in the Fleas (Pulicidæ), which are wingless flies with hard, com-

pressed bodies, with two simple eyes instead of compound eyes, a sucker-like arrangement of mouth parts, and hind legs specially adapted for leaping. By many writers the Fleas are regarded as constituting a distinct order—"Aphaniptera" (ἀφανίζω, *aphanizo*, "to hide;" πτερον, *pteron*, a "wing"). Other anomalous forms of the Diptera are seen in the Horse-ticks (*Hippobosca*), Sheep ticks (*Melophaga*), Bird-ticks (*Ornithomyia*), etc. These have a horny flattened body, flat head, large eyes, rudimentary antennæ, and a proboscis formed by the labrum and maxillæ. They are parasites, and differ from all other insects in their mode of development. Each female produces only one or two larvæ, and when first hatched the larva is not divided into rings, but is smooth and egg like, the whole covering being a puparium like case in which the larva becomes a pupa immediately after it is born. The spider-shaped Bat-ticks (Nycteribidæ), which are parasites on the Bat, and the Bee lice (Braulina), minute, wingless, blind insects, parasites on Bees, are other anomalous forms of the Diptera.

Coleoptera.—The Coleoptera (κολεός, *coleos*, a "sheath;" πτερόν, *pteron*, a "wing") or Beetles are insects whose upper or anterior wings, called elytra, are more or less horny, and they meet in a straight line upon the top of the back: and in general there is a small triangular piece, called scutellum, between their bases. Their hind or under wings are thin, and when not in use are folded longitudinally and transversely. The Coleoptera have two pairs of jaws, which move sidewise, and the larvæ, which are called grubs, undergo a complete transformation in coming to maturity. There are probably more than 100,000 species of these insects, and they present a great diversity of form, size, color, structure, and habits.

Some kinds, as the Tiger Beetles (Cicindelidæ), have a large head, globose eyes, long antennæ, and toothed mandibles, and are very rapacious in their habits, devouring other insects, which constitute their principal food. Their larvæ are provided with powerful jaws, and, like the adults, are rapacious in their habits. These larvæ dig vertical holes in the ground, in which they remain, the head just fitting the entrance, and when any insect passes near enough they seize it and devour it.

Cicindela campestris (Imago and Larva).

The Predaceous Ground Beetles (Carabidæ) are also rapacious, and several species are known as Caterpillar Hunters, on account of the warfare which they wage against various kinds of lepidopterous larvæ.

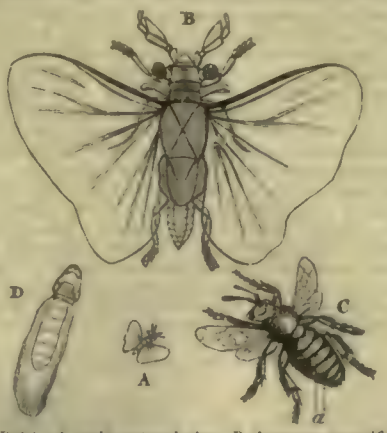
Other kinds of beetles, as the Dytiscidæ, are fitted for a residence in the water, and these have their hind legs specially fitted for swimming. They are also exceedingly rapacious, both in the larva and in the adult state, devouring all kinds of small aquatic animals, even fishes.

Other kinds of beetles, as the Gyrindæ, are found moving in all sorts of curves and gyrations on the smooth surface of standing waters; and these too swim by means of the fringed hind legs.

Some kinds, as the Carrion Beetles (Silphidæ), are true scavengers. Living together in great numbers, they perform a most useful service in removing noxious substances. Some species of this family have the habit of burying all the small dead animals which they find. They dig beneath the animal till they sink it out of sight, then deposit their eggs in it; and as soon as the young hatch, the latter begin to devour it, and thus the noxious substance is soon converted into living tissues.

The Dermestidæ are small beetles which in the larva state attack skins and bodies and all parts of dried animals. They often commit great havoc in zoological collections.

The Horn-bugs (Lucanidæ) are beetles whose head is very large and broad, and whose upper jaws are very large, curved, and often branched. They fly only in the night. In the grub state they live in the roots and trunks of trees, and some of the species are six years in coming to maturity.



But of all the groups of the Coleoptera, the Scarabæans (Scarabæidæ) are one of the most extensive. Here belong the May-Beetle, Rose Chafers, Goldsmith Beetles, and a host of others. They differ from one another in many important respects, but agree in having a rather short convex form, the antennæ ending in a knob composed of three or more leaf like pieces, a visor-like piece which extends forward over the face, and their legs are fitted for digging.

The Buprestians (Buprestidæ) are beetles which have the head apparently sunk into the thorax nearly up to their eyes, and the whole form somewhat flattened and very solid. The lustre is metallic, more or less bronze-like. They are found on trees, and feign death when disturbed. In the larva state they bore the peach, plum, pine, oak, hickory, etc.

The Elaters (Elateridæ) are also beetles which have a hard body, and their head sunk to the eyes in the thorax, and the latter is as broad as any part of the body. In the larva state they are called wire-worms, and in this state they devour roots and wood. In the adult state they have attracted much attention from their habit of springing upward with a jerk after they have been placed upon the back.

Some of the representatives of the Coleoptera are very important in their relations to pharmacy. This is true of the Cantharides (Meloidæ), extensively used for blistering purposes. They have a broad head, long antennæ, and soft wing-covers, which are more or less bent downward.

The Stylopidæ are minute beetles, so apparently abnormal in their appearance and structure that they have by some naturalists been referred to a distinct order called

Stylops Dalii: *A*, male, natural size; *B*, the same magnified; *C*, a bee, with the head of a stylops (*a*) projecting from between the abdominal rings: *D*, female, magnified.

"Strepsiptera" (from στρεψις, *strepsis*, a "twisting," and πτερόν, a "wing"). In the larva state these beetles live as parasites in the body of the bee.

Of the small members of the Coleoptera, none are more destructive than the Weevils (Curculionidæ). Some kinds of weevils attack the pea, others the plum, others grain, others rice, others stored grain, and others the pine, etc. All of the Curculios are hard-shelled, and the fore part of the head is generally prolonged into a slender snout, at the extremity of which is the mouth armed with small horny jaws. In the larva state they are white grubs.

The Long-horn Beetles (Cerambycidæ) are those which have exceedingly long antennæ. When caught they generally make a squeaking noise. The larvæ are wood-borers, and they are the most destructive of all wood-eating insects. In some species they are three or more years in coming to maturity as larvæ; they then go into the pupa state in their burrows, and at length appear as adult beetles. To the Long-horns belong the Oak-Pruner (*Stenocorus villosus*, Fabr.), the Beautiful Clytus (*Clytus speciosus*, Say), the Painted Clytus (*Clytus flexuosus*, Fabr.), the Apple-tree Borer (*Saperda bivittata*, Say), etc.

A large number of beautiful, golden, green, and blue beetles are included under the name of Chrysomelidæ. Their form is hemispherical or oval, the head is sunken, and the antennæ are wide apart. All of these are gayly colored.

And lastly we may notice the Lady-birds (Coccinellidæ) as representatives of the Coleoptera. These are small beetles, more or less hemispherical in form, and of a black, red, or yellow color, ornamented with spots. They are rapacious in their habits, both in the larva and in their adult state, devouring plant-lice.

Hemiptera.—The Hemiptera (ἡμι, *hemi*, "half;" πτερόν, *pteron*, a "wing") are insects which have the mouth parts in the form of a slender horny beak, consisting of a horny sheath enclosing three sharp bristle-like organs, the whole being fitted for a sucking apparatus. When not in use this beak is bent under the body, and lies upon the breast. Bugs, Cicadas, Plant-lice, etc. are familiar examples of this group of insects. The Bugs may be regarded as the typical members of the group, as their wings are thick in their basal portion and thin towards their tips; that is, in general terms, half of the wing is of one degree of thickness, and the other half of another degree, and hence the name Hemiptera. As the wings of Bugs thus differ in the two regions, basal and terminal, these insects are often called Hemiptera heteroptera.

On the contrary, other hemiptera, as Cicadas, Plant-

lice, etc., have the wings of uniform thickness throughout, and they do not lie flat upon the back, as in the Hemiptera heteroptera; and having wings of uniform thickness throughout, they are called Hemiptera homoptera. Of the Hemiptera homoptera, few if any are more interesting than the Cicadas or Harvest-flies (Cicadidæ). These insects have a broad head, large eyes, and three eyelets on the crown. Both pairs of wings are transparent and distinctly veined. The males are furnished with an apparatus by which they produce a loud buzzing sound. This apparatus consists of a pair of organs which have been aptly compared to a pair of kettle-drums—one situated in each side of the abdomen, and each formed of convex pieces of a parchment-like membrane, finely plaited, and played upon by means of muscular fibres fastened to the inside; and thus, by the rapid contraction and relaxation of these fibres, the drum-heads are alternately tightened and loosened, and the sounds above named produced. And it may be added here that the intensity of the sounds is greatly increased by other cavities within the body, formed, or at least separated, by thin transparent membranes. The female cicadas are provided with a piercer for perforating the limbs of trees, in which they lay their eggs. This piercer consists of three pieces—two outer ones, which are grooved on the inside, and toothed on the outside like a saw, and a central piece, which is a sort of spear-pointed borer, which moves freely between the other two.

The Cicadas have attracted much attention from very early times. The Greeks, we are told, were charmed with their "singing;" and they often kept these insects in cages that they might enjoy their "music." And the Greeks also used them as food, eating both the pupæ and the perfect cicadas. Our common species are the Dog-day Cicada or Harvest-fly (*Cicada canicularis*, Harris) and the Seventeen-year Cicada (*Cicada septendecim*, Linn.), often incorrectly called the Seventeen-year Locust. It is believed that the latter insect appears in the same locality only at intervals of seventeen years, and hence its specific name. The Seventeen-year Cicadas come in swarms in the early part of summer, and the forests then resound with their singing from morning till night. After pairing, the females lay their eggs. Selecting small branches, they clasp them with their legs, and then they repeatedly thrust their piercers obliquely into the bark and wood in the direction of the fibres, and at the same time they detach little splinters of wood at one end, and these serve as a fibrous cover to the perforations. After thus forming a fissure, they deposit therein from ten to twenty eggs, which are conveyed to their places by means of the grooved side-pieces of the piercers. When one fissure is filled, another is made and filled, and so on, till each female has deposited her whole stock of four or five hundred eggs. When the eggs hatch, the young fall to the ground and immediately burrow to the roots of the tree, upon whose juices they subsist. They live in this way till the time of their transformation approaches, when they gradually ascend towards the surface, and at length they leave the ground, generally or always in the night, and crawl up the trunks of trees, where they fix their feet firmly to the bark. Their covering is now dry and hard. After some effort they open a longitudinal fissure in the skin of the back, and through this opening the perfect Cicada comes forth, leaving its dry and empty pupa skin attached to the tree.

European Cicada.

Other examples of the Hemiptera homoptera are seen in the little Tree-hoppers (Cercopidæ) which are found upon grass, herbs, and trees, upon the sap of which they subsist, imbibing such quantities that it oozes out of their bodies in the form of little bubbles, thus soon covering the insect in a mass of frothy foam. Of all the Hemiptera, none are more remarkable than these for their curious, and, in many cases, grotesque forms.

Of the very small and minute Hemiptera homoptera, none perhaps are more remarkable than the Plant-lice (Aphidæ) and the Bark-lice (Coccidæ). The former have on the hind part of their short body two minute tubes or pores, from which exude minute drops of a sweet fluid. And this fact explains the reason why ants collect in great numbers wherever plant-lice abound, for the ants delight to feed upon this honey-like fluid, and the most friendly relations exist between these two kinds of insects. The ants even caress the plant-lice with their antennæ, apparently soliciting them to give out the sweet fluid; and it is stated, on what seems to be good authority, that an aphis or plant-louse has been seen to give a drop of fluid to each of a number of ants waiting to receive it! The Aphidæ multiply with astonishing rapidity, and in this multiplication they admirably illustrate what has been called Parthenogenesis.

It is well understood among physiologists that it is the contact of the male sperm-cell with the yolk, which fertilizes the egg, and that from the moment of this contact the life of the embryo, which is to be the future animal, begins. This fertilization of the female germ by means of the male element through the pairing of the sexes, is the general rule among bisexual animals. But among insects there are exceptions, so that in some species an embryo may, and does, begin its life without the interposition of the male; and this mode of reproduction has been called by Owen, Parthenogenesis.

The young aphides are hatched in the spring from impregnated eggs laid the previous autumn, and soon they come to maturity, and the whole brood consists of wingless females. These females bring forth living young, each female producing in some cases twenty in a day. These young are also wingless females, and soon they bring forth living young, which are also wingless females, and in their turn bring forth living young. And in this way brood after brood is brought forth, even to the fourteenth generation, in a single season; and this, too, without the appearance of a single male. But the latest brood in autumn is composed of both males and females, which have wings; these pair, stock the plants with eggs, and then perish. We get some idea of the rapidity of the multiplication of these animals when we remember that Réaumur has proved that a single plant-louse may become, in five generations, the progenitor of 6,000,000,000 descendants!

The Bark-lice (Coccidæ) are Hemiptera in which the males alone are winged; the females always remaining in a sort of scale-like form, such as may be found at all times on the apple tree. Coccidæ are famous for the dyes which they have furnished the world for hundreds and even thousands of years. They furnished the *Kokkos* of the Greeks, the *Coccus* of the Romans, the *Kermes* of the Arabs, the *Alkermes* of the Persians; and the *Scarlet Grain* of Poland and the *Cochineal* of Mexico are insects of this family of the Hemiptera.

Some kinds of the Hemiptera, as the Boat-flies (Notonectidæ), live in the water, and are noted for their habit of swimming on their backs; others, as the Scorpion-bugs (Nepidæ), live in the water, and are adapted for seizing prey by their fore legs, which flex upon themselves, and thus act as pincers; others, as the Water-measurers (Hydrometridæ), are found on the water, over the surface of which they move with a gliding motion.

To the Hemiptera also belong the Squash-bugs (Coreidæ), the minute insects included in the Thripsidæ, the Bed-bugs (Cimicidæ), and the Lice (Pediculidæ).

Orthoptera.—The Orthoptera (ὀρθός, *orthos*, "straight," πτερόν, *pteron*, a "wing"), named from the nature of their wings, which lie straight along the back, have their upper wings rather thick, the under ones the larger and thinner, and folded in plaits like a fan. As already shown in our general remarks, they do not undergo a complete transformation, but they pass by insensible gradations from the larval to the adult stage, all the while remaining active.

Some kinds, as the so-called Earwigs (Forficulidæ), have the body flattened and armed at the hind extremity with a pair of pointed nippers. Others, as the Cockroaches (Blattidæ), have the body broader, flattened, and the hind extremity furnished with conical articulated appendages.

Others, as the Walking-sticks and Walking-leaves (Phasmidæ), closely resemble twigs and leaves. Others, as the Mantes (Mantidæ), are much elongated, and have the fore legs formed for seizing and holding prey; and they sit for hours holding up their fore legs, ready to seize any insect within their reach. Still others, as the Crickets (Gryllidæ), have an oblong flattened body, long stylets at the hind extremity of the body, and the females are provided with a very long ovipositor for introducing their eggs into the ground; and the males have the membranes and nervures

The Crested Locust (*Locusta cristata*).

at the base of the wings so specialized that, by the rubbing the wings upon each other, they can produce a sound known as a chirrup. Others, as the Locusts (Locustidæ), are grasshopper-like, and have very long antennæ and four jointed tarsi, and the females have a long ovipositor. Some kinds of the Locustidæ, as *Anthophilus*, are wingless and live under stones; others, as the Katydid (*Cyrtophyllus concavus*, Scudder), have the wings broad in the middle, and concave; others, as the Oblong Leaf-winged Grasshoppers (*Phylloptera*), have the wing-covers shorter than the under wings; others (*Phaneroptera*) have the ovipositor curved sharply upward; others (*Conocephalus*) have the head ending in a conical projection; and others (*Orchelimum*) have the ovipositor sabre-like in form.

The Migratory Locusts and their allies (*Acrydii* of Latreille) are orthoptera which have a large head, short antennæ, three-jointed tarsi, instead of four-jointed, as in the Locustidæ, and they have no projecting ovipositor. Such are the Red-legged Locusts (*Caloptenus*), the Coral-winged, and the Carolina Locusts (*Œdipoda*), etc.

Neuroptera. — The Neuroptera (*νεῦρον, neuron*, a "nerve;" *πτερόν, pteron*, a "wing") have a long body, and four long, thin, membranous, and finely-netted veined wings, the anterior pair generally, or at least sometimes, being the smaller; in some genera, however, the hind pair is the smaller, or even obsolete. These insects have large eyes and large mandibles. They are destitute of weapons, except their jaws, being without a sting or piercer. Most of the Neuropters are aquatic in the larva and pupa state. Many species do not undergo a complete metamorphosis.

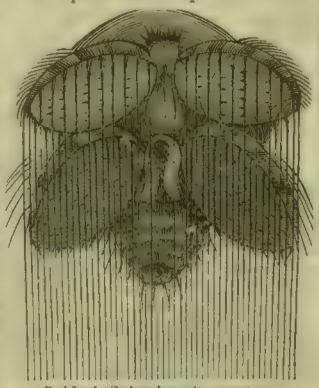
Some of the representatives of the Neuropters, as the White Ants or Termites (Termitidæ), inhabit only warm countries, and in the larva state feed upon wood, devouring all kinds of wooden furniture, and even whole houses, as they have done in the Isle of France. Those called Stone-flies (Perlidæ) are oblong, depressed, and have many-jointed antennæ, and the abdomen has two long-jointed appendages. In the larva and pupa state they are found under stones in the water. Some families, as the May flies (Ephemeridæ), are very short lived, living in the imago state scarcely more than a few hours or a day, although their larva and pupa state extends through several years, all of which they pass in the water.

The Dragon-flies (Odonata) are among the best representatives of the Neuroptera, and have a long body, exceedingly large eyes, powerful jaws, and large and lustrous wings. They fly with great velocity and remain long upon the wing. In the larva and pupa state they live in the water; and when the time comes for them to complete their transformation, they crawl up the stems of plants, and, having withdrawn from the pupa skin, which remains fixed to the plant, and having become dry, they fly swiftly away. At all periods of their life they are exceedingly rapacious, feeding upon all insects which they can capture.

To the Neuroptera also belong the Horned Corydalis and its allies (Sialidæ), the Ant-lions and other Lace-wings (Hemerobini), and the Caddice-flies (Phryganidæ). The Ant-lions are famous for the pitfalls which, while in the larva state, they make in the sands, and at the bottom of which they lie concealed, all but the jaws, and there await insects which fall into their pit; these they at once seize and devour.

Some of the Neuropters are wingless, and are called degradational forms, and closely resemble the Myriapoda. Such are the Spring-tails (Thysanura or Podaridæ), which have a cylindrical scaly or hairy body, short and four- to six-jointed antennæ, four to eight simple eyes on each side, and whose anal bristles are united and bent under the body, forming a sort of spring by means of which these insects leap. They are seen in gardens, and also on the surface of pools of water. Such also are the Bristle-tails (Lepismatidæ), which have a long body covered with silvery-like scales, and the abdomen furnished with three long bristles. They are found among old books and woollens, and also under stones and rubbish in damp situations. The species of both these families are small, the largest rarely having bodies over an inch in length.

Dragon-fly (*Æschna*).



Arachnida. — The Arachnida are insects which have the body divided into only two well-marked regions, the head and the hind-body, the head and thorax being closely united into one piece, thereby resembling in this respect the head and thorax of the Crustaceans. The Arachnids have simple eyes, four pairs of legs, attached to the thorax, and they are without antennæ, compound eyes, and wings; and they do not change in general form in coming to maturity, which they reach after moulting the

skin six times. The Arachnids are divided into three sub-orders:

1. *Araneina*, or Spiders proper.
2. *Pedipalpi*, or Scorpions.
3. *Acarina*, or Mites.

Araneina.—The Araneina (*aranea*, a "spider"), or Spiders proper, have mandibles formed exclusively for biting, a more or less spherical abdomen, which is not divided into segments, and this abdomen is attached to the cephalothorax by a slender pedicel. They perform their respiration by means both of lungs and tracheæ, and they undergo no metamorphosis in coming to maturity. The mandibles end in a powerful hook, in the end of which there is an opening to a duct which connects with a poison-gland situated in the head. The palpi resemble shorter legs; they are in fact the maxillæ. In the female they are simple, but in the male the terminal joint is modified so as to be a sexual organ. Most species of Spiders have eight ocelli, but some have only six, some have only two, and certain cave species are said to be blind.

One of the most curious things about Spiders is their silk-spinning apparatus. On the abdominal extremity there are from four to six protuberances, each of which is perforated with a great number of minute holes—in some species as many as a thousand in each protuberance. From these minute holes passes the adhesive fluid or liquid silk, which has its origin in internal reservoirs; and as soon as the fine streams of this material come to the air they harden into silk. It is said that the Spider has the power of uniting all the minute fibres into one or into several threads, according to the use it would make of the silk. The Spiders' webs are very curiously constructed, and well repay the most careful observation and study.

Spider's Spinning-Apparatus, magnified.

The eggs of Spiders are enclosed in cocoons spun from the same kind of material of which they construct their webs, and the form of the egg-cases or cocoons varies according to the species. The young remain in the cocoon for a long time, and grow to double the size which they have when hatched, apparently without food.

The Tetrapneumones are large hairy spiders which have four lung-sacs and four stigmata, and two pairs of spinnerets. They live in cylindrical holes which they make in the earth. They are found mainly in warm climates. Here belong the Trap-door Spiders, described by some writers under the name of Territelariæ, or "Under-ground Weavers," and by others under the name of *Mygale*. These spiders are named from the fact that they close the entrance of their burrows with a sort of trap-door. This door is made of earth lined beneath with silk, or in some species it is wholly of silk.

The Dipneumones, including all true spiders except the preceding family, have two lung-sacs, two or four stigmata, and three pairs of spinnerets. Some of the species of this family are known as the "Wanderers," others as the "Sedentary" spiders. The latter spin webs, and watch them that they may secure prey. Some kinds (*Clubione*) construct tubes of silk under the bark of trees and under stones. Others, as the Water Spider (*Argyroneta aquatica*, Linn.) of Europe, live under the surface of the water, there making their nest, which is filled with air. Others (*Tegenaria*) make a horizontal web, connected with which is a tubular retreat, where the spider remains till some fly or other insect becomes entangled in the web. Those belonging to the genus *Theridion* have the four inner ocelli larger than the four outer ones, and the first and last pair of legs longest; and they make webs of threads crossing in all directions. The genus *Epeira* includes those which have a large globular abdomen. They are sedentary species, constructing a web formed of spiral threads, and other threads radiating from a centre. *Nephila* is a genus of large spiders characterized by a long, cylindrical abdomen. *Nephila plumipes* of the Southern States has become celebrated from the interesting experiments made with it by Dr. B. G. Wilder, in the production of silk. The genus *Thomisus* includes "wanderers" which have very small chelicerœ. *Dolomedes* includes wanderers which hide under stones, and not unfrequently dive under water, and which make an orbicular cocoon which is carried by the mother. *Lycosa* is a genus of large hairy spiders, with large chelicerœ, with the fourth pair of feet the longest, and the third pair shortest. The species make no silk. They hide under stones. The Tarantula belongs to this genus. The genus *Salticus* includes the leaping Spiders; they have a large square cephalothorax, and the hind-body is of an oval cylindrical form.

The Tarantula of Europe, *Lycosa tarantula*.

Pedipalpi.—Here belong the Scorpions and allied forms. They have the maxillary palpi greatly enlarged, and in most cases ending in forceps, and their abdomen is distinctly jointed; and in the true scorpions the hind-body is very long, and ends in a curved point or sting which discharges a poisonous fluid contained in an internal reservoir.

The True Scorpions (Scorpionidæ) have enormous forceps-like maxillæ. The False Scorpions (Pseudo-scorpiones) are minute forms which have maxillary palpi resembling the claws of the true Scorpions. They are often found in old books and in neglected drawers. The Harvestmen, or Daddy Long-legs (Phalangidæ), have a cephalothorax which is not jointed, the abdomen is short and thick, and the maxillary palpi end in a single claw, and the mandibles end in forceps, and their legs are excessively elongated.

Acarina.—The Acarina or Mites are arachnids which have oval or rounded bodies which exhibit no articulation or divisions into segments, the cephalothorax and abdomen being merged together. Most of the species are very minute in size; a few, however, as the Ticks—which are the largest of all—attain the length of half an inch. The Red Mites (Trombididæ) are common in hot-houses and in hot-beds, and in the dry warm beds of the garden. The Water-mites (Hydrachnidæ) are found in both fresh and salt water. The Ticks (Ixodidæ) are large mites with leather-like bodies, and they attach themselves to man and animals, especially in warm countries. Some species, however, are found in temperate regions. Of the true Mites (Acaridæ), we may mention the Sugar-mite (*Tyroglyphus sachari*), common in unrefined sugar; the Cheese-mite (*Tyroglyphus siro*), the Flour-mite (*Tyroglyphus farinæ*), the Itch-mite (*Sarcoptes scabiei*); the last being the insect which, by burrowing and breeding under the skin, causes the loathsome disease which bears its name: and to the true Mites belong various species inhabiting domestic animals, and which entomologists refer to the genus *Dermatodectes*; and here also belongs the curious animal known as the Nose-mite, which buries itself in the follicles of the human nose.

Myriapoda.—The insects which belong to this order are more or less worm-like, and are composed of ten to two hundred or more segments. The head is free from the body, and is similar to that of typical insects. They may be divided into two sub-orders:

1. *Chilopoda*.
2. *Chilognatha*.

Chilopoda.—The sub-order of Chilopoda (χεῖλος, *cheilos*, a "lip," and πούς, ποδός, *pous*, *podos*, a "foot"), or the highest group, includes those myriapods which have each segment or ring simple, and bearing but a single pair of feet, and which have the head divided into two regions, one before and the other behind the mouth. To this sub-order belong the so-called "Earwigs" (Lithobiidæ), which have a broad and flat head and forty-jointed antennæ, and which feed mainly upon earth-worms; the Centipedes (Scolopendridæ), which have from twenty-one to twenty-three feet-bearing segments, and which in some species, as those of the tropics, are six to nine inches long; and the Geophilidæ, which are characterized by their slender form, and by their great number of segments, varying in the different species from thirty to two hundred, each formed of two complete sub-segments, and bearing only a single pair of feet.

Chilognatha.—The Chilognaths (χεῖλος, *cheilos*, a "lip;"

γναθος, *gnathos*, a "jaw") have very short and few-jointed antennæ, very numerous segments, and each segment has two pairs of feet. Here belong the Millipedes, also known as "Thousand Legs" (Julidæ), which have the body long, nearly cylindrical, and made up of numerous nearly equal segments. And here also belong the Polydesmidæ, which have the body broad and flattened and the head large; and the Glomeridæ, which have the form of the body half cylindrical, and composed of twelve or thirteen segments, the head large and free, the first thoracic ring small, and the last ring of the body shield-shaped.

And now, having given a brief outline of the nature and of the history of the science of Entomology, and having described and illustrated a few of the more important typical forms of which it treats, we leave the subject with our readers, commending it as one worthy of the attention of the ablest minds. SANBORN TENNEY.

Entomos'traca [from the Gr. ἔντομον, an "insect," and ὄστρακόν, a "shell"], one of the orders of crustaceans, including those species having normally five or six cephalic segments in the form of a shell, and five or more rings of the foot series, the hinder ones being generally obsolete. The abdomen has no appendages. The species of this division are very numerous, and most existing species are of small size, except the king-crab (*Limulus*), which some recent theorists place in a new order by itself. Many of them are found in fresh and salt water, and some are parasitic. They differ greatly in general form, and in the number of their organs of locomotion, which in some species are more than 100, and in others are entirely absent. The order includes the carcinoids, ostracoids (with the cirripeds), limuloids (doubtful), and rotifers. Entomostracous shells are peculiarly abundant in certain palæozoic rocks. They first appear in the Silurian strata.

Entozo'a [from the Gr. ἐντός, "in" or "within," and ζῶον, an "animal"], a name applied to those animals which dwell within the bodies of other animals. They belong to the Vermes (true worms), the lowest form of articulate animals. They are divided into (1) cestoid worms, or tapeworms, which are all more or less jointed, of a ribbon-like form, each joint of hermaphrodite conformation, and dwelling in the intestines. The embryonic worms penetrate the tissues, become surrounded by a cyst, and are known as "cystic" worms. They have no alimentary canal. (2) The flukes or trematode worms, of flat oval form, smooth, soft, and not jointed. They have an hermaphrodite development, the sexual organs pervading a great part of the body of the adult. They afford many wonderful examples of the so-called alternate generation and of parthenogenesis in some of the generations. The disease called "rot" in sheep is caused by their presence in the biliary passages. In man they cause the hæmaturia prevailing at the Cape of Good Hope and the endemic dysentery of Egypt. They inhabit the liver, kidneys, lungs, etc. Among the genera are *Distoma*, *Bilharzia*, and many others. When perfect, they have an alimentary canal without vent. (3) The Nematelmia or round worms, having long, cylindroid forms, and in the more perfect forms an intestinal canal with mouth and vent, and distinct sexes. This class includes pinworms, *Ascarides*, the *Trichina*, the Guinea worm, and many others.

Entre Douro e Minho ("between the Douro and the Minho," rivers which bound it on the S. and N. respectively), a province of Portugal, is bounded on the N. by Spain, on the E. by Traz os Montes and Beira, on the S. by Estremadura, and on the W. by the Atlantic. Area, 2808 square miles. It is the most populous, the richest, and the best cultivated province of the kingdom. Everywhere are fertile valleys, rich meadows, fields, and vineyards. The products are fruit, wine, oil, figs, oranges, barley, rye, and wheat. Chief town, Oporto. Pop. 988,985.

Entre Rios, ĕn'trā ree'ŏs (*i. e.* "between the rivers"), a province of the Argentine Republic, is bounded on the N. by the province of Corrientes, on the E. by the river Uruguay, and on the S. and W. by the Paraná. Area, 52,110 square miles. The surface is level, and partly occupied by swamps and prairies or grassy plains. Many cattle and horses feed on these plains. The chief exports are hides, horns, and tallow. Pop. in 1869, 134,271. Capital, Concepcion.

Entry, the act of entering. In criminal law, in addition to breaking, entry is necessary to constitute the crime of burglary, but this need not be with the whole body. If the hand or any part of the body goes into the building with intent to commit a felony, it is sufficient; and if only the instrument intended to be used in the commission of the crime enters, it is enough to constitute the offence.

In the law of real estate, entry is the taking actual possession of land. A writ of entry was a common-law action, now disused, to recover the possession of land from one who wrongfully withheld it. Any going upon the land of another is often termed an entry, and unless done with the permission of the owner, is in most instances unlawful and a trespass.

En'velope [from the Fr. *envelopper*, to "wrap up," to "cover," "enclose"], in geometry, a curve or surface generated by the repeated intersections of given curves or surfaces, whose position, form, and magnitude are allowed to vary according to some invariable law. A tubular surface is the envelope generated by a moving sphere of constant radius; the plane curve is the envelope of its tangent, etc.

Envelopes, for letters, are a comparatively recent development of civilization, the demand for them having been created by cheap postal service. They were at first cut, folded, and gummed by hand, but the great call for them stimulated the production of machines for doing the work. These machines are of various kinds; and, not to specify the names of the somewhat numerous rival inventors, it may be remarked that in latter years these machines turn out surprising numbers of envelopes, and that the quality of the work is absolutely perfect—very far ahead of what could be done by hand. Stamped envelopes for letters and newspapers are issued and sold by nearly all civilized governments, but the products of private enterprise are more generally used.

En'voy [from the Fr. *envoyer*, to "send" (that is, to "put or start on the way"), from *en*, "in" or "on," and *voie*, "way"], a person sent on any mission, but particularly one sent on business to a foreign court; a diplomatic minister of the second order; one who is inferior in rank to an ambassador, and who cannot demand a private audience of the sovereign to whom he is accredited, but must negotiate with the minister of foreign affairs. Besides the ordinary envoy, there is a class of diplomatists styled envoys extraordinary and ministers plenipotentiary.

Envoy Extraordinary and Minister Plenipotentiary, the title of the principal representatives of the U. S. government at the capitals of the following nations: Great Britain, France, Russia, Germany, Austria, Italy, Spain, China, Brazil, Mexico, Peru, and Chili. They rank next below ambassadors and next above ministers resident. They are appointed by the President and confirmed by the Senate. Their salaries are as follows: ministers to Great Britain and France, each $17,500 annually; to Italy, Peru, and Chili, $10,000; to the other countries mentioned, $12,000.

Eny'o [Gr. Ἐνυώ], the goddess of war in the Greek mythology. (See BELLONA.)

Enz'ina (or **Encina**), **de la** (JUAN), a popular Spanish poet, born in Old Castile in 1468. He was patronized by King Ferdinand V. In 1496 he published a volume containing several comedies and odes and a poem called a "Vision of the Temple of Fame." He is considered the founder of the Spanish theatre. Among his dramas, which are remarkable for purity of style and natural imagery, is "Placida y Victoriano." He performed a pilgrimage to Palestine in 1519. Died in 1531.

Enzio, or **Enzo,** a natural son of the emperor Frederick II. of Germany, was born about 1224. He fought for his father against the pope and the Guelphs, and assumed the title of king of Sardinia. Having obtained command of the imperial fleet, he gained a great naval victory over the Genoese in 1241. In 1249 he was taken prisoner by the Guelphs, who confined him until his death in 1272.

E'ocene [from the Gr. ἠώς, "dawn," and καινός, "recent;" that is, belonging to the dawn of the cenozoic period], in geology, a term applied to the lower tertiary strata, and originally suggested by the occurrence in those strata of a few faint dawnings of living species of fossils. The term was originally limited by the percentage (3½) of recent or living to extinct species found in a collection of older tertiary shells of the Paris basin, but it is now known that all the eocene species are extinct. The eocene beds rest on the chalk, and occupy small areas compared with the older formations. They are generally well developed in the vicinity of the three great capitals of Western Europe, London, Paris, and Brussels, each of which is built on a special tertiary basin of this period. They contain many interesting fossils of vertebrates, mollusks, radiata, etc. The eocene strata are divided into upper, middle, and lower eocene. The London clay belongs to the lower division.

In America the eocene strata form a belt of outcrop extending from New Jersey around, parallel with the Atlantic and Gulf coasts, to the Mississippi, and are represented in the interior of the continent by certain estuary and freshwater deposits of Wyoming Territory, etc. On the west coast the eocene has not been distinctly recognized. In

Eastern America the eocene strata are divided into the Claiborne, Jackson, and Vicksburg beds, of which the last are most recent. They contain numerous fossils, mostly marine mollusks, but also include some gigantic vertebrates, as *Zeuglodon cetoides*, a carnivorous cetacean seventy feet in length, and *Carcharodon megalodon*, a shark of which the teeth are sometimes six inches in length. Leaves and fruits occur in the eocene at Brandon, Vt., and in Mississippi. Like the flora of the European eocene, they indicate a tropical or sub-tropical climate. The eocene beds of Wyoming have furnished the remains of a remarkable group of mammals, which are thought by Prof. Marsh to form a new order, which he has named "Dinocerata." The largest of these (*Dinoceras mirabilis*) had the bulk of an elephant, and was provided with three pairs of horns and a pair of great sabre-like canine teeth. Many other vertebrate remains from these deposits have been described by Profs. Marsh and Cope.

Eolian Harp. See ÆOLIAN HARP.

Éon de Beaumont, d' (CHARLES GENEVIÈVE LOUIS AUGUSTE ANDRÉ TIMOTHÉE), called **Chevalier d'Éon,** a French diplomatist and writer, born at Tonnere Oct. 5, 1728. He was employed in an important mission to Russia in 1755, and served as captain in the French army in 1759. About 1761 he became minister plenipotentiary in London, but he was soon deprived of that office by secret intrigues of his enemies in Paris. He remained as an exile in England for many years, during which much sensation was excited by a report that he was a female. He returned to France in 1777, after which he wore the female dress, in compliance, it is said, with the order of the king. He died poor in London May 21, 1810.

Eon (or Eudo) de Stella, a fanatic of the twelfth century, an ignorant (and perhaps insane) nobleman of Bretagne, who, having heard, during the act of exorcism, the words "through Him" (*per Eum*, etc., in Latin) "who will come to judge the quick and dead," concluded, from the resemblance between his own name *Eon* and the Latin *Eum*, that he was the one appointed as the final judge of mankind. He taught a reformed doctrine, and gained many disciples. He was captured in 1148, and many of his followers (called Eonians) were burned, but Eon himself was pronounced insane, and seems to have been spared.

E'os [Gr. Ἠώς, the "dawn"], in the Greek mythology, a daughter of Hyperion, a sister of Helios (the sun), and the wife of Tithonus. She corresponds to the Latin Aurora, the goddess of the morning. (See AURORA.)

Eötvös, or **Eoetvoes** (JOSEPH), FREIHERR VON, an eminent Hungarian author and statesman, born at Buda Sept. 3, 1813, was educated at the University of Pesth. About the age of twenty he produced "Revenge," a tragedy, and two successful comedies entitled "The Critics" and "The Wedding." His "Carthusian" (1838–41), a novel, was generally admired. He also gained distinction as a political writer and orator of the popular party. Among his works are a political novel entitled "The Village Notary" (1844–46), which was translated into English, a work on the "Equal Rights of Nationalities" (1851), and another on "The Influence of the Ideas of the Nineteenth Century" (2 vols., 1851–54). He was minister of public instruction in 1848, but he resigned the same year. In 1865 he began to edit a political paper. In 1867, after the reconciliation between the Magyars and the emperor of Austria had been effected, he was again appointed minister of public instruction, which place he retained until his death. Died Feb. 2, 1871.

Eozo'on [from the Gr. ἠώς, the "dawn," and ζῶον, an "animal," implying an animal existing at the dawn of creation], one of the oldest geological representatives of animal life, a gigantic marine animal whose remains have been found in the Laurentian rocks of Canada. The *Eozoon Canadense* belonged to the Foraminifera, animals of very low organization, even lower in the scale than sponges. It had no proper organs, but consisted probably of a jelly-like mass, having the power of secreting a calcareous shell. It was doubtless sessile, adding as it grew crust after crust of chalky matter, probably living on from age to age until it constituted whole beds of limestone. What are supposed to be other species of *Eozoon* have been found in the oldest rocks of Europe. The organic character of *Eozoon* is denied by many palæontologists.

Epacrida'ceæ [from *Epa'cris*, one of the genera], a natural order of exogenous plants (shrubs and small trees), mostly natives of Australia, Polynesia, and the Indian Archipelago. They resemble Ericaceæ in many respects, but differ from them in the structure of the anther, which is 1-celled and destitute of appendages. The leaves are parallel-veined and have no midrib. The corolla is generally tubular; the fruit is in many cases an edible berry, in others a capsule or drupe. The *Lissan'the sap'ida* bears an edible fruit, which is called the Australian cranberry. Several species of *Epacris* are cultivated in greenhouses for their very beautiful flowers. This order also comprises the *Sphenotoma*, *Lysinema*, *Styphelia*, and many other genera.

E'pact [Gr. ἐπακτός, "added," from ἐπάγω, to "bring to"], the excess of the mean solar month (the twelfth part of a tropical year) over the mean lunar synodical month, or mean lunation; that is, inasmuch as the mean lunation is less than the mean solar month, the epact is properly the amount to be added to the former to bring it up, or make it equal, to the latter. Practically, in the Church calendar, however, the epact is the number of days which intervene between the end of the ecclesiastical year in December and the first day of January succeeding; or, as it is commonly expressed, the epact is the age of the moon, estimated in entire days, at the beginning of the civil year. According to the definition given first above, it is manifest that the epact must increase from month to month, but for the purposes of the ecclesiastical calendar this monthly increase is not considered; the entire increase for each year being supposed to take place at the end of the year. This calendar is extremely artificial, the calendar moon being a sort of fiction of which the periods only approximately correspond with those of the moon in the heavens; so that the calendar months and the true or mean astronomical lunar months rarely begin or end exactly together. In the reckoning of the epact the following arbitrary assumptions are made: 1. The mean synodical month is 29½ days long (it is, in fact, 44 minutes 2.84 seconds longer). 2. The lunar year consists of 12 lunar months, or 354 days. 3. The solar year is always 365 days (it is really 5 hours 48 minutes 46.05444 seconds longer). 4. The calendar months are alternately 30 days and 29 days long. Thus, the first day of the second ecclesiastical month is the 31st of January; the first day of the third ecclesiastical month is the 1st of March; of the fourth, March 31st; of the fifth, April 29th, and so on. Thus, the last day of the lunar year is December 20th; so that if new moon occurs at the beginning of the civil year exactly, the epact at the beginning of the next civil year is 11. In another year this epact will be doubled, and become 22; and at the end of a third it will be 33 days, or more than a month; so that on the 1st of January the moon will be somewhat advanced in a second lunation. The completed lunation is counted 30 days, and the epact is thus reduced to *three* days at the beginning of the fourth year. The month thus passed over, or dropped, is called an *embolismic* month. As the epacts accumulate, six such embolismic months of 30 days each are dropped; and finally we reach a point where the epact is 29, which we consider to be a complete embolismic month also, and drop it; so that the next following year begins with the epact 0, like the first. This occurs at the end of the nineteenth year, so that in every cycle of nineteen years the epacts recur in the same order.

All the foregoing assumptions are separately inexact, but in combination their inaccuracies nearly balance each other; and accordingly it happens that, at the end of the nineteen-year cycle, the calendar moon, the true moon, and the sun occupy almost exactly the same relative places as at the beginning. That is, supposing the sun and the true moon to leave some determinate point—say the equinox—together at the beginning of the cycle, then at the end of the nineteenth year or the beginning of the twentieth the sun will be truly in the equinox again, and the moon very nearly so, but not quite, being behind by about two hours and four and a half minutes. In something less than twelve cycles (about 220 years), therefore, the true moon will have lost a day on her epact. If the calendar moon lost nothing, its epact would consequently be too great. But the calendar moon loses more than the true moon, as will appear from the following comparison, made for a period of four cycles, or 76 true astronomical (tropical) years and 940 lunations:

940 calendar lunations, of 29½ days each, give	27,730 days.
24 embolismic months too long, and 4 too short, add	10 "
19 intercalary days, ignored in the lunar calendar	19 "
Total days in 4 calendar cycles	27,759.000
" " 940 true lunations	27,758.753
" " 76 true years	27,758.407

It thus appears that the calendar moon falls behind the true moon 0.247 of a day, or nearly 6 hours, in 76 years; and its epact not only absolutely diminishes, but diminishes relatively to that of the true moon also. The effect of this is to cause the successive calendar new moons to occur too late by an amount slowly but constantly increasing; the increase amounting to one entire day in something more than 4 times 76, or 304 years—more exactly 308 years. No account of this circumstance was taken, however, for nearly sixteen centuries after the commencement of our era. At the time of the reformation of the calendar by Pope Gregory XIII., in 1582, the epact had become too small by nearly five days.

It was not this discrepancy, however, which led to the reformation, though occasion was taken at that time to cor-

rect it. The real cause which prompted the action of Pope Gregory was the observation that, through the error of the Julian intercalation (of one day in every four years—every leap-year, as it is called), the adjustment of the months to the seasons was becoming slowly displaced, the equinox going backward towards the first of March. At the time of the Council of Nicæa (A. D. 325) the equinox fell, or was supposed to fall, on the 21st of March; in 1575 it fell upon the 11th. A retrogradation of ten days had occurred in 1250 years. Pope Gregory thought it expedient to put back the equinox again to the 21st, which he could do in no other way than by adding *ten* to the count of every day in the year; and this he accordingly did. It did not matter at what place in the year the change of count began. He actually commenced by calling the fourth day of October, 1582, the fourteenth day of that month. This change has had no other practical effect but to perplex systematic chronology. The displacement of the seasons had not become so great as to occasion any inconvenience. It *was*, however, desirable to provide against any further displacement for the future; and this part of Pope Gregory's reform is only to be spoken of in terms of admiration. The Julian intercalation of one day in every fourth year produces an error of excess in the calendar year, which by accumulation amounts to about three-quarters of a day in a century, or three days in every four centuries. The intercalary day is, therefore, in the Gregorian system, omitted in the centurial years which are not multiples of 400, and retained in those which are. The dropping of an intercalary day has the effect to make the succeeding year begin a day sooner than it otherwise would, and it therefore diminishes the moon's epact by the same amount. The Gregorian correction of the civil year accordingly requires a reduction of the epact by three days in every four hundred years. If the epact, as it had been previously reckoned, had been truly adjusted to the astronomical year, this correction would be all that would be necessary to keep it permanently right. But in point of fact the Julian intercalation made the mean year too long, in reference to the moon, by about six hours in 76 years, or one day in 304 years (if the more exact numbers are taken, one day in 308 years), making the epact correspondingly too great. The principal mathematician employed on the calendar by Pope Gregory, Christopher Clavius, made the period 312½ years, which would give eight days in 2500 years. To correct the epact *to the Julian year*, therefore, it is necessary to add to it eight days in every twenty-five centuries; and to correct it from the Julian to the true year, it is necessary to subtract three days in every four centuries. In 100 centuries the epact is accordingly increased by 32 days, and diminished by 75 days, the diminution amounting on the whole to 43 days. The larger of these corrections, called the solar, which is subtractive, is applied of course in each non-bissextile centurial year. The smaller has to be applied at periods regulated by arbitrary rule. As 25 is not divisible by 8 without a remainder, the intervals between the corrections cannot be entirely uniform. There are seven intervals of three centuries each, and an eighth of four centuries. The first application of this correction after the promulgation of the Gregorian reformation was made in 1800, which century was assumed to end one of the periods of twenty-five. The correction is to be made at the end of every third century after 1800, until 3900, after which it will be deferred till the year 4300. In the Church Prayer-Book, at the end of the introductory matter relating to the calendar, there are three tables called General; of which the second embraces the resultant effect of these corrections of the epact up to the end of the eighty-fifth century, when the correction amounts to one entire embolismic month of thirty days.

The use of the epact of the year in the calendar of Pope Gregory was to lead to the determination of paschal full moon, and so, by consequence, of Easter. (See EASTER.) The epact being the age of the moon in entire days at the beginning of the (lunar) month, the place of new moon in March would be found by counting backward from the 30th of March (which we have seen to be the last day of the third lunar month), including this 30th day itself in the count, a number of days equal to the epact. The date in March thus found is the *first* day of the moon, and thirteen days more added bring us to the fourteenth; the day of March thus found will be the date of paschal full moon, unless it happens to be less than the 21st. In this latter case we must go to the month of April, and count backward from the end of the fourth lunar month, which is April 29th. To facilitate this counting backward, or to make actual counting unnecessary, Clavius introduced a row of numeral letters into the calendar page opposite the days of the month, in reversed order, I. being opposite March 30, and XXX., or 0, standing opposite March 1. This is extended through all the months in the year, as in the following illustration, which presents the months of March and April only:

Day of Month	March. Epact.	Letter.	Day of Month	April. Epact.	Letter.
1	0, or XXX.	D	1	XXIX	G
2	XXIX.	E	2	XXVIII.	A
3	XXVIII.	F	3	XXVII.	B
4	XXVII.	G	4	XXVI., 25	C
5	XXVI., 25	A	5	XXIV., XXV.	D
6	XXV.	B	6	XXIII.	E
7	XXIV.	C	7	XXII.	F
8	XXIII.	D	8	XXI.	G
9	XXII.	E	9	XX.	A
10	XXI.	F	10	XIX.	B
11	XX.	G	11	XVIII.	C
12	XIX.	A	12	XVII.	D
13	XVIII.	B	13	XVI.	E
14	XVII.	C	14	XV	F
15	XVI.	D	15	XIV.	G
16	XV.	E	16	XIII.	A
17	XIV.	F	17	XII.	B
18	XIII.	G	18	XI.	C
19	XII.	A	19	X.	D
20	XI.	B	20	IX.	E
21	X.	C	21	VIII.	F
22	IX.	D	22	VII.	G
23	VIII.	E	23	VI.	A
24	VII.	F	24	V.	B
25	VI.	G	25	IV.	C
26	V.	A	26	III.	D
27	IV.	B	27	II.	E
28	III.	C	28	I.	F
29	II.	D	29	0, or XXX.	G
30	I.	E	30	XXIX.	A
31	0, or XXX.	F			

In this little table one peculiarity will attract attention. Though the third lunar month has thirty days, and the fourth only twenty-nine, yet each has thirty epact numbers. There seemed to be a necessity for this; otherwise, when the epact is XXIX. it would be equivalent to zero in the short months (the hollow months as they were called), but not so in the full months. The epacts XXIV. and XXV. are therefore placed opposite the same day. During the same cycle three consecutive numbers like XXIV., XXV., and XXVI. will never all be found among the epacts. When XXIV. and XXV. are both present, XXVI. will be absent; and in that case XXV. is transferred to the place of XXVI., as indicated by the Arabic numeral 25 opposite that epact. Thus, notwithstanding this duplication, two epacts will never fall on the same day of the month. (For a more full explanation of this matter, see the little treatise by the writer of this article, entitled "How to Find the Church Festivals.")

The use of epacts for finding paschal full moon and Easter is not very convenient. The simple rules given in the article on EASTER in this volume will be found much more so. But this is a suitable place to explain how to find the value of the numerical term proper to be used in calculating the date of paschal full moon in the article referred to. The General Table II. of the Prayer-Book, above spoken of, contains the resultant corrections of the epact for all the centuries from 1600 to 8500. From 1600 to 1700 this correction was zero. From 1700 to 1800, and further from 1800 to 1900, it is 1; and in subsequent centuries it goes on, somewhat irregularly, to increase. Now, the numerical term in the formula given in the article EASTER for computing the date of paschal full moon (when the golden number is odd) is at present 10, from 1600 to 1700 was 9, and after 1900 will be 11. It is, in short, always 9, increased by the correction of the epact found in the General Table II. just mentioned; which for convenience we may call the secular correction of the epact. And an extremely simple rule for finding this numerical term is the following: *From the number of the centuries in the given year of our Lord take its fourth part and its third part (disregarding fractions), and increase the result by* TWO. This is true up to 4200. But in that year and the centuries following, up to 6700, the number of the century must be diminished by *one* before taking the *third* part. In other respects the rule remains unaltered. In 6700 and the centuries following, up to 9200, the number of the century must be diminished by *two* before taking the third part. In 9200, and up to 11,700, the rule is the same as given at first, except that the result is to be increased by *three* instead of *two*. The Gregorian calendar will, however, itself require correction before the year 4000. As an example, let it be required to find the numerical term for the computation of paschal full moon during the century beginning with 4100 and ending with 4200. Putting N for this term, we have $N = 41 - \frac{1}{4}(41) - \frac{1}{3}(41) \cdot 2 = 41 - 10 - 13 \cdot 2 = 20$. In General Table II. of the Prayer Book we find opposite to 4100 the number 11. And $11 + 9 = 20$, thus verifying the statement made above.

F. A. P. BARNARD.

Epaminon'das [Gr. Ἐπαμεινώνδας or Ἐπαμινώνδας], an illustrious Greek statesman and general, born at Thebes about 418 B. C. He was a pupil of Lysis, a Pythagorean

philosopher. His youth was passed in retirement and study. He was temperate and virtuous, and is said to have despised riches. He formed an intimate friendship with Pelopidas. In 385 he served with distinction at the battle of Mantinea, after which he passed many years in private life. He was one of the deputies sent by Thebes in 371 B. C. to a congress of the Grecian states, in which he opposed the policy of Sparta and defended the interest and rights of Thebes in an eloquent speech. War speedily ensued between Sparta and Thebes, and Epaminondas was chosen commander of the Theban army, which amounted to only 6500 men. He defeated the Spartans in 371 B. C. at the battle of Leuctra, which was fatal to the supremacy of Sparta. In this action he displayed great military genius, and owed his success partly to his novel manœuvres and combinations. He invaded Peloponnesus in 369, and marched against Sparta, which was defended with success by Agesilaus. He commanded the Theban army which defeated the Spartans at Mantinea in 363 B. C. (or, as some say, 362), but he was killed in this action. He left a pure and exalted reputation as a patriot, a statesman, and a sage, and is universally admitted to have been one of the greatest captains of antiquity. Cicero expressed the opinion that Epaminondas was the greatest man that Greece has produced. (See Cornelius Nepos, "Epaminondas;" Grote, "History of Greece," chaps. lxviii., lxix., and lxxx.; E. Bauch, "Epaminondas und Theben's Kampf um die Hegemonie," 1834.)

Epanome'ria, a town at the N. W. point of the island of Santorini (*Thera*) in the Grecian Archipelago. The houses are partly excavated in the face of a cliff of pozzuolana which is nearly perpendicular and is close to the sea. The lowest of fifteen tiers of houses is about 400 feet above the sea.

Ep'arch [Gr. ἔπαρχος, from ἐπί, "upon" or "over," and ἀρχή, "government"], in ancient Greece the title of the governor of a province, a ship's master, a satrap, or the prefect of a region under the Roman rule. The province itself was called an eparchy. In modern Greece the primary subdivision of a nomarchy is called an eparchy. In Russia an eparchy is the diocese or archdiocese of a bishop or archbishop of the Greek Church.

Epaulement [Fr., from *epaule*, "shoulder"], a military term which, from its derivation, would signify, as defined by Webster, a *side* work, a work to cover *sidewise*—*e. g.* a *traverse*, or a short parapet made at the flank of a battery or end of a parallel; but practically its meaning is extended to any covering made of earth, stone, wood, or iron, when intended simply as a screen—*e. g.* to cover cavalry waiting to be brought into action. (See Mahan, "Military Engineering.")

Epaulette, an ornamental article of uniform of military and naval officers, worn on the shoulders, as the name indicates; a plate or strap extending along the shoulder from near the collar, and terminating with a fringe of gold or silver bullion, which falls over the shoulder. Rank is indicated by the size of the bullion and by devices on the strap, such as stars, anchors, crowns, etc. In the American army the epaulette, hitherto worn by officers of all grades (as still in the navy), is now confined to general officers, its place being supplied, for the lower grades, by the "shoulder-knot" of gilt cord. The practice varies in the different services of Europe.

E'pe, a town of the Netherlands, province of Guelderland. Pop. in 1867, 7705.

Épée, de l' (Charles Michel), Abbé, a French teacher of the deaf and dumb, was born at Versailles Nov. 25, 1712. He was a Jansenist preacher, and for some time canon at Troyes. About 1755 he began to devote himself to the gratuitous instruction of the deaf and dumb. He is said to have been the first who used gestures or the language of signs in their education, on which subject he wrote several treatises. He founded in Paris an institution which was successful. Died Dec. 23, 1789.

Epeirus. See Epirus.

Epei'ra [from the Gr. ἐπί, "on," "together" and εἴρω, to "fasten"], a genus of spiders belonging to the Epeiridæ, are distinguished for the brilliancy of their colors and the geometric regularity of their webs, which are formed by concentric circles and straight radii. *Epeira diadema* is a large species found in Great Britain. These spiders are very numerous in tropical countries, where they grow to great size. Several species occur in the U. S.

Eperies, ā'pĕr-yĕsh or ā'pā-re-ĕsh, or **Heperjes** [Lat. *Eperiæ* or *Fragopolis*], an old town of Hungary, the capital of the county of Saros, is on the river Tarcza, about 148 miles N. E. of Pesth. It is surrounded by walls, and is one of the most beautiful towns of Upper Hungary. It is a bishop's see, has five churches, a college, and manufactures of linens, woollen goods, and earthenware. A royal salt-mine is worked in the vicinity. Pop. in 1869, 10,772.

Épernay, ā'pĕr'nā' [Lat. *Aquæ Perennes*], a town of France, in the department of Marne, on the river Marne, about 80 miles E. by N. from Paris. It is on the railway from Paris to Chalons, 20 miles W. N. W. of the latter. It is well built, clean and well paved, and has a town-hall and a public library. Here are manufactures of hosiery, earthenware, and refined sugar; also many elegant villas, with wine-vaults. Épernay is a great entrepôt or market for champagne wine, which is produced in the vicinity. Pop. 11,704.

Eper'ua, a genus of trees of the order Leguminosæ, one species of which (*Eperua falcata*), called wallaba, is abundant in Guiana. Its hard, durable, heavy, resinous timber, which is of a bright red-brown color, with white veins, is much used for shingles. The tree has pinnate leaves and a regular monopetalous flower.

E'phah, a Hebrew measure of capacity containing 27.83 pints, or three English pecks and three pints.

Ephem'era [from the Gr. ἐφήμερος, "lasting for a day" (from ἐπί, "on" or "for," and ἡμέρα, a "day")], a genus of neuropterous insects, commonly called day-fly or may-fly, are allied to the dragon-flies or Libellulidæ. In the larva and pupa states they live a year or more in the water, but their existence in the perfect state is very brief. They are used by anglers as bait. They give name to the family Ephemeridæ, of which many species occur in the U. S.

Ephem'eris [Gr. ἐφημερίς, a "diary," from ἐπί, "on" or "for," and ἡμέρα, a "day"], **Astronomical Ephemeris, Nautical Almanac.** Ephemeris and almanac are chiefly applied to two distinct classes of publications. An almanac is usually an annual which gives a calendar of the civil and ecclesiastical divisions of the year, with the dates of festivals and fasts and other days of special commemoration, and for each day or some longer interval the times of passing the meridian and of the rising and setting of the sun, moon, and principal planets, and their places in the zodiac, together with the phases of the moon and the times of eclipses and other important astronomical phenomena. With these is combined a variety of other matter, according to the special object of the publication. The astronomical tables which almanacs contain are ordinarily given with little precision, and are for the most part adapted only to a particular latitude. Such tables are said to have been constructed even in the time of Ptolemy. They were indispensable to the astrologers of later days, who doubtless had them for finding the positions of the planets at some future or past date, compiled with sufficient accuracy to make their prognostications.

Since the invention of printing, almanacs have appeared in large numbers in every part of the civilized world. They supplied an extensive popular demand, but added to the real information which they contained astrological and meteorological predictions, and other matter much more objectionable.

The "British Almanac," published by the Society for the Diffusion of Useful Knowledge, for the year 1828, introduced a decided reform in this class of works. And now there are many, and in all civilized countries, which contain valuable statistics of various kinds and essays on various subjects, such as are adapted to the classes of readers for which each may be specially designed. Some of them have a permanent value as works of reference. The "Tidal Almanac" of the U. S. Coast Survey is an example of a special class.

An ephemeris of a fixed star is a table of its apparent right ascension and declination at equal intervals of time. An ephemeris of a primary body of the solar system gives for each day, or for some regular longer or shorter interval, its direction and distance from the earth or sun, or both. The apparent semi-diameter, horizontal parallax, phases, and degree of brilliancy may also be given at stated intervals. The ephemerides of satellites give their positions with reference to their primaries, with their occultations, eclipses, and transits.

Observations furnish the data for computing the elements of a planet's orbit, and the ephemeris is prepared either directly from these elements or from tables derived from them, constructed to facilitate computations, and in which the attractions of other bodies are taken into account. The places of the planet tabulated in the ephemeris, whether for past or future times, may readily be compared with those derived from observations; and thus, as observations accumulate, the astronomer may determine more accurately the planet's orbit, and by a new and more trustworthy ephemeris again subject the theory of its motion to the test of observations. The history of astronomy furnishes an instructive example of the alternate improvement in the means and methods of observation, and the advance of

theory and scientific knowledge. At one time observations are more precise than theory; at another, the theory of the motions of a heavenly body may give its position more accurately than any single observation. It has been by such successive advances, alternately in theory and in the precision of observations, that practical astronomy has attained its present approximation to perfect accuracy. Tables of some of the planets are extended to several centuries in the future, with full confidence that an astronomer of those remote times will find them not only within the field of his telescope, but near its centre.

An astronomical ephemeris is a collection of such ephemerides for a particular year or series of years, with the times of eclipses, occultations, and other astronomical phenomena, or the means of determining them. The more complete works of this kind are intended to furnish the astronomical observer, whether at an observatory, in the field of a survey, or at sea, with all the data relating to the sun, moon, planets, and some of the principal fixed stars, which he needs to facilitate the prosecution of his work. From the design of some of them, and the special adaptation of portions to the wants of navigators, they are also called "nautical almanacs."

Although prepared for a particular meridian, they can readily be adapted to any other by interpolating for the difference of longitude or of the local times of the two meridians. Their use, therefore, is general, and not restricted to any part of the earth.

The earliest astronomical ephemeris noticed in astronomical bibliographies is that of Iarchus in 1150; the first printed ephemerides were published in 1475 for the years 1475 to 1506, and in 1499 for the years 1475 to 1531, though doubtless portions were prepared earlier; both were prepared by Regiomontanus. The latter extends through three cycles of nineteen years, and gives the longitudes of the sun and moon, and the phases of the moon and of eclipses occurring from 1483 to 1530, with explanations and useful tables. These have been the precursors of a succession of ephemerides, defective at first, but improving as astronomy advanced.

The "Connaissance des temps ou des mouvements célestes," commenced by Picard for the year 1679, has appeared for each succeeding year, without interruption, to the present time. Additions and improvements were made by La Lande in 1760, who subsequently added lunar distances, with the design of making it more useful at sea. This and almost all the subsequent volumes have been enriched by valuable memoirs by the most eminent French astronomers, thus carrying out the purpose of La Lande to make this annual a journal of astronomy. For many years it has been prepared under the direction of the Bureau des Longitudes of France. Improvements have been made in it from time to time by the use of more precise tables in its preparation. At present it is under the immediate supervision of M. Mathieu, and is among the most valuable of this class of works.

The "Nautical Almanac and Astronomical Ephemeris," published by the British Admiralty, was commenced by Maskelyne for the year 1767. He undertook its preparation, after a plan sketched by La Caille, for the purpose of meeting the wants of navigators, and especially of supplying facilities for using the method of finding the longitude by the distance of the moon from the sun or a star, which Halley had proposed in 1731. Mayer's new tables of the moon for the first time gave the moon's place with sufficient precision to make this method available. The successive annual volumes have been issued, usually three years in advance, to the present time. It was not until 1834 that it came up to the requirements of an astronomical ephemeris. Other improvements and additions have since been made. Under its present superintendent, Mr. J. R. Hind, new tables of the sun, moon, and all but two of the planets have been introduced, so that it has no superior either as an astronomical ephemeris or an almanac for the use of navigators. Many of its volumes contain valuable contributions to practical astronomy by English astronomers.

The "Berliner Astronomisches Jahrbuch" first appeared for the year 1776, and has been continued by Bode, Encke, and its present superintendent, Prof. Foerster, without interruption. It was mainly designed to supply the wants of astronomers, though those of the navigator were not overlooked. As an astronomical ephemeris it was in advance of all others until the later improvements in its British contemporary. Its volumes contain valuable astronomical memoirs from many of the most distinguished German astronomers. Of later years it has contained ephemerides of most of the asteroids.

The preparation of the "American Ephemeris and Nautical Almanac" was begun in 1849, under the superintendence of Lieutenant (now Rear-Admiral) Davis, U. S. navy, in accordance with an act of the Congress of the U. S. The theoretical portions of the work were placed under the special direction of Prof. Benjamin Pierce of Harvard University. The construction of tables of the moon and of some of the planets, with corrected elements and in a form which would facilitate the computation of their ephemerides, was first undertaken, and so successfully accomplished that from its commencement the "American Ephemeris" has ranked among the highest works of this class in extent, completeness, and adaptation to the wants of astronomers and navigators. The first volume was for 1855. In the preparation of later volumes new and more accurate tables of the sun and planets (except Jupiter and Saturn) have been employed. Several of its volumes contain valuable papers by American astronomers.

It consists of two parts—the first arranged specially for the use of navigators, and computed for the meridian of Greenwich; the other prepared for astronomers, and adapted to the meridian of Washington. The first part is also published separately. Tables of the moon, Mercury, Venus, the standard stars, and four asteroids have also been published. The preparation of ephemerides of twenty-three asteroids discovered by American astronomers has also been undertaken.

Prof. Joseph Winlock, U. S. navy, now director of Harvard Observatory, succeeded Admiral Davis in the charge of the work; in 1866 it was placed under the direction of the writer of this article. The successive volumes have appeared for each year without interruption, and that for 1876 was published in Sept., 1873. Several of them contain valuable memoirs. The continuance of the work is dependent upon annual appropriations by Congress.

J. H. C. Coffin.

Ephe'sians, The Epistle of Saint Paul to the, was written probably in the year 61 or 62, during the apostle's first imprisonment at Rome, and shortly after the Epistle to the Colossians. The words ἐν Ἐφέσῳ, "at Ephesus" (i. 1), are wanting in the "Codex Sinaiticus" and some other manuscripts, but the weight of diplomatic evidence on the whole preponderates in their favor. The absence of personal greetings is not so easily explained. It is one of the richest and most glowing of the Pauline Epistles. The first three chapters are doctrinal; the last three, hortatory and practical. Of the many commentaries which have been written, those of Harless (German), 1834–58, and Eadie (Scotch), 1854, are among the best.

R. D. Hitchcock.

Eph'esus [Gr. Ἔφεσος: Fr. *Éphèse*], one of the twelve cities of the Ionian confederation, stood on the river Cayster, which falls into the Gulf of Scala Nova on the western coast of Asia Minor. Its earliest traditions connect it with the birthplace of the goddess Diana, which was probably in the immediate vicinity of the site selected for the famous temple, one of the Seven Wonders of the ancient world. Amazons are said to have been the earliest priestesses of Artemis (Diana), and Herodotus tells us that Hercules founded a city in the Ephesian territory B. C. 1250. Androclus the Athenian (B. C. 1044) drove out the inhabitants, and with his followers established a Greek colony. Ephesus increased in importance with the culture of the worship of Diana, which attracted multitudes from all parts, who remained to worship at the shrine of the goddess and to benefit themselves by the commerce of the city, which became the chief mart of Asia and the metropolis. Ephesus was in turn ruled by tyrants, oligarchies, and republics. It paid tribute to Persia for two centuries from the time of Cyrus (B. C. 558–529) to Darius III. Ephesus was chiefly remarkable for its magnificent temple dedicated to Diana, which was burnt by Eratostratus in B. C. 356, the day Alexander the Great was born. The Romans finally possessed themselves of this and other cities in Asia Minor (B. C. 41), and under Cæsar Augustus and the succeeding emperors the city was rebuilt. The city was sacked by the Goths A. D. 262. The temple was then destroyed, and from that time the city declined in importance. For many centuries it was in the hands of various adventurers, and it declined into a mere suburb when the Turks built a considerable town at Ayasalouk towards the end of the thirteenth century. The explorations which were directed by Mr. John T. Wood, an English architect, for the British government from 1863 to 1874, resulted in very important discoveries; 462 Greek and Latin inscriptions were brought to light, and the remains of the famous temple were discovered by him 22 feet below the present surface. Mr. Wood found remains of three temples which were built successively on the same site. N. E. of the city, and at the foot of the hill at Ayasalouk, the foundations and some of the cellar walling of the temple built B. C. 500, and described by Pliny as having been laid on charcoal and fleeces of wool, were found. Four feet above the pavement of this temple was found the pavement of the temple burnt by Eratostratus, and the pavement of the peristyle of the last

temple was found 7 feet 6 inches above the most ancient of these three temples, which were discovered by Mr. Wood to be of the same size. The last temple was raised upon a platform 9 feet 6 inches high, which was ascended by fourteen steps. The temple itself was 164 feet wide and 343 feet long, with 100 columns in the peristyle 6.0½ in diameter; 36 of these were sculptured with figures life-size, some of the columns having as many as ten figures in their circumference—others had only four or five. Mr. Wood found in the ruins of the city the remains of Saint Luke's tomb. The large theatre was 495 feet in diameter, and seated 24,500 persons. The Odeon was 153 feet in diameter, and seated 2300 persons. Many interesting tombs and other remains were found, and the British Museum has been much enriched by the results of these explorations. JOHN T. WOOD.

Ephial'tes, the name of a famous giant in the Greek mythology, said to have been a son of Neptune.

Eph'od [from the Heb. *aphad*, to "put on"], a Jewish robe or tunic worn originally by the high priest; afterwards by all priests. It was made of fine linen. The ephod of the high priest had a breastplate attached to it containing twelve precious stones, on which were engraved the names of the twelve tribes. The relation of these twelve stones to the Urim and Thummim is still an open question.

Eph'ori, or **Eph'ors** [Gr. ἔφοροι (sing. ἔφορος, from ἐπί, "on" or "over," and ὁράω, to "see"); Lat. *ephori*], the title of magistrates common to many of the Dorian states of ancient Greece. In the political constitution of Sparta the ephors exercised supreme power. The Spartan ephors were five in number, and were elected from the body of the ruling caste. Their term of office was one year. Besides their judicial authority, they exercised a control over the functions of the kings and the senate, and sometimes recalled the former from their foreign expeditions. They negotiated treaties with foreign states, and possessed nearly all the executive power of the government.

E'phraem (or **Ephraim**) THE SYRIAN [Lat. *Ephræ'mus Sy'rus*], a celebrated ecclesiastic and writer, born at Nisibis, in Asia Minor. He was a young man when he attended the Council of Nice in 325 A. D. He was a zealous opponent of Arianism, became a hermit or anchorite in the prime of life, and lived in a cave near Edessa. He was venerated as a saint and a prophet by his contemporaries, and received the offer of the bishopric of Edessa, but he declined it. He wrote in Syriac numerous religious works, among which are hymns and commentaries on Scripture. Died about 378 A. D. His works were published in Syriac and Greek at Rome by the Assemani, in 6 vols., 1732–46. A German translation of a selection of his works was published by Zingerle (6 vols., 1830–37).

E'phraim, one of the Hebrew patriarchs, was the second son of Joseph, and the head or founder of one of the twelve tribes of Israel. The territory of the tribe of Ephraim extended from the river Jordan to the Mediterranean Sea, and was bounded on the N. by Manasseh and on the S. by Benjamin and Dan; and was about 55 miles from E. to W. by 70 from N. to S.

Ephraim City, a post-village of San Pete co., Ut., 8 miles N. N. E. of Manti.

Ephra'ta, a post-township of Lancaster co., Pa. Pop. 2695. In the eighteenth century Ephrata was for a long time the centre of a religious denomination called the Seventh-Day German Baptists. Ephrata Springs are a pleasant summer resort for health and pleasure.

Ephra'tah, a post-township of Fulton co., N. Y. It has manufactures of leather. Pop. 2207.

Ep'icarp [from the Gr. ἐπί, "upon," and καρπός, "fruit"], in botany, the outermost layer of the pericarp or fruit. When the walls are separable into three layers, the outer layer is named either exocarp or epicarp.

Epichar'mus [Gr. Ἐπίχαρμος], an eminent Greek poet and philosopher, born in the island of Cos about 540 B. C., was a pupil of Pythagoras. He removed about 485 B. C. to Syracuse, where he passed the greater part of his mature life. According to Aristotle, he was the inventor of comedy. Plato assigns him as high a rank among comic writers as that of Homer among epic poets. Epicharmus wrote, besides dramas, treatises on philosophy, mythology, etc. He appears to have been an original genius and elegant writer. His works are not extant. Died about 450 B. C. (See O. MÜLLER, "The Dorians;" HARLESS, "De Epicharmo," 1822.)

Ep'ic Po'etry, or **The Ep'os,** is that class of poetry which relates the history of a series of events, taking the series as a whole, apart from what precedes or follows. Epic poetry is chiefly of a narrative nature, and represents the subject of which it treats as a unit, with a definite beginning and an end. In a wider sense, epic poetry comprises the ballad, the romance, and even the fable, but in its more limited use it may simply denote the popular legends and tales of a nation or tribe which have been collected and arranged. Of the Greek epics, two only, the "Iliad" and the "Odyssey," have come down to us, and the study of these has helped us very much to understand the true nature of the epic. Until the close of the last century, Homer was regarded as the original author of these epics. But in 1795 F. A. Wolf, a learned German philologist, broached the theory that the poems of Homer were not the work of one, but of many poets. In fact, they appear to be, to some extent at least, a collection of Greek legends and tales, arranged (as is now generally admitted) by the master-mind of a great poetic genius. A similar origin must be predicated for the Hindoo epics "Râmâyana" and "Mahâbhârata," the "Shah Nameh" of the Persian Firdousee, the Finnish "Kalevala," and the German "Nibelungen."

From the manner in which it originated, the nature of the epic is easily deduced. As the poetical summation of the popular legends of a race or tribe, in which all the thoughts and feelings of the race are depicted, it must embody the peculiarities of the nation, and must be a complete and true picture of the life and doings of a race. Thus it is that in the same nation different epics may exist. While, for instance, the "Iliad" is a collection of the war-legends of the Greeks, the "Odyssey" treats of the family life and travels on land and on sea. But as the epic must be such a complete picture, and must be, in contrast to the former legends, a complete whole, it takes from the primitive history of the nation a prominent fact as a central figure, and groups around this the single legends; and this centre is only the frame which holds together the single, otherwise unconnected, legends.

This form of an epic is only possible in the early youth of a nation, when the legends still circulate among the people and are believed by them. But there have nevertheless been attempts at epics in later times, which have been the work of a single poet. This is the difference between Virgil and Homer. Among the more prominent epic poets of modern times are Dante, Ariosto, Tasso, Camoens, Milton, and Klopstock. But the more practical and prosaic the world becomes, the more this form of poetry will disappear, and it is only a romantic or a comic epic, like Byron's "Don Juan," that will be successful in these days, while the novel takes the place of the epic. (See ZIMMERMANN, "Ueber den Begriff des Epos," 1848.)

Epicte'tus [Gr. Ἐπίκτητος; Fr. *Épictète;* Ger. *Epiktet;* It. *Epitetto*], an eminent Stoic philosopher, born at Hierapolis, in Phrygia, about 60 A. D. He was in his youth a slave of Epaphroditus, a favorite of the emperor Nero, and lived at Rome. He became a freedman, and was banished with other philosophers from Rome by Domitian in 89 A. D., after which he lived at Nicopolis in Epirus. He was a man of excellent moral character, and acquired a high reputation as a teacher of philosophy, but he wrote little if anything. His temper and doctrines were less austere than those of most other Stoics, and were essentially Christian in their nature. It does not appear, however, that he had any connection with the Christian Church, or that he was a believer in the mysteries of that religion. Among his favorite maxims was "Suffer and abstain." His disciple Arrian collected his maxims and doctrines in a work called "Enchiridion," which has been translated into English by Mrs. Carter (1758), and by T. W. Higginson (1865). (See RITTER, "History of Philosophy;" G. BOILEAU, "Vie d'Epictète et sa Philosophie," 1655, in English by J. DAVIES, 1670; FARRAR, "Seekers after God," 1869.

Epicure'an Philos'ophy, a system of philosophical teaching which took its name from Epicurus (337–270 B. C.), its founder. It originated in a reaction against the teachings of Socrates and his followers. Throughout the period of Greek decline and the last ages of republican Rome it exercised a profound influence, which was perpetuated through the days of the Roman empire, in spite of the opposition of Stoicism and of Christianity. It is a remarkable fact that it always remained substantially as Epicurus left it.

The writings of Epicurus are lost, with the exception of fragments chiefly preserved by Cicero, Seneca, and Diogenes Laertius, but the sublime poem of Lucretius, "De Rerum Naturâ," is an exposition of the teachings of Epicurus.

In theology, Epicureanism was essentially atheism. The gods were eternal, immutable, and entirely unconscious of human affairs. Human responsibility for wrong-doing was consequently reduced to the minimum. The highest positive duty was made to be the pursuit of pleasure—not necessarily sensual enjoyment, for Epicurus himself taught that repose was the highest pleasure. Whatever the virtues of Epicurus may have been, the results of his system of ethics were thoroughly bad. The moral corruption of ancient Greece

and Rome was in part the fruit of this system. The genial temper, the elegant habits of life, and the moral indifference exhibited in the writings of Horace were among the least objectionable of the effects of the widespread Epicurean teachings. It is not too much to assert that Epicureanism produced not one thoroughly admirable character in ancient history.

The physical doctrine taught by Epicurus and Lucretius was not unlike that of certain modern evolutionists. They held that matter is uncreated, indestructible, and that all material things were self-evolved, without a supervising or directing Intelligence. (See LUCRETIUS, "De Rerum Naturâ;" GASSENDI, "Syntagma Philosophiæ Epicuri;" and HENNE'S article "Épicure" in the "Dictionnaire des Sciences Philosophiques.")

Epicu'rus [Gr. Ἐπίκουρος], a celebrated Greek philosopher, the founder of the Epicurean sect, was born in the island of Samos in 337 (or, as some say, 341) B. C. He was a son of Neocles, an Athenian, and is said to have been a pupil of Xenocrates, but he professed to be self-taught. He visited Athens at the age of eighteen, afterwards travelled in Ionia, and opened a school at Mitylene, where he taught new doctrines. About the year 306 he removed to Athens, where he purchased a garden and founded a celebrated school of philosophy. He was very popular as a teacher, and gained a great number of disciples. He recognized pleasure as the chief good, and consequently was calumniated by the Stoics, but it appears that his habits were temperate and virtuous. His physical philosophy was based on the atomic theory of Democritus. He treated ethics as the most important department of philosophy, and studied nature with an ethical rather than a scientific purpose. He opposed the popular superstition, and refused to recognize the gods of the Greek mythology, but taught that the gods live in a state of passionless tranquillity, and give no attention to sublunary affairs, which they consider beneath their notice. Epicurus took no part in political affairs. He wrote numerous works on ethics, natural philosophy, etc., which are not extant, but several of his letters have been preserved by Diogenes Laertius. His opponents admitted that he was personally amiable and virtuous. Our knowledge of his doctrines is derived chiefly from the works of Cicero and Lucretius, who in his poem "De Rerum Naturâ" amply illustrates his philosophy, and expresses great admiration of Epicurus. Among the eminent men who favored Epicurean principles were Horace, Atticus, Gassendi, Rousseau, and Voltaire. Died in 270 B. C. (See GASSENDI, "De Vita et Moribus Epicuri," 1647; RITTER, "History of Philosophy;" G. H. LEWES, "Biographical History of Philosophy.")

Ep'icycle [from the Gr. ἐπί, "upon," and κύκλος, a "circle"], in ancient astronomy, a circle having its centre moving along the circumference of another circle. It was a favorite opinion of the Greek astronomers that all the celestial motions must be uniform and circular, because the circle is the most perfect of plane figures. The phenomena of the stations and retrogradations of the planets were apparently inconsistent with this notion; and in order to explain them, Apollonius of Perga imagined the theory of *epicycles* and *deferents*. He supposed every planet to move uniformly in the small circle or epicycle, the centre of which is carried uniformly forward along the circumference of the large circle or deferent, of which the earth occupies the centre. Hipparchus, having discovered the eccentricity of the solar orbit, supposed the motions to be performed in eccentric circles. The celebrated astronomer Ptolemy adopted the hypotheses both of Apollonius and Hipparchus; that is, he supposed the earth to be placed at a small distance from the centre of the deferent circle (which consequently was called an *eccentric*), and the planet to move uniformly in the epicycle, the centre of which also moves uniformly in the deferent. By means of these suppositions, and by assigning proper ratios (determined by observation) between the radius of the deferent and the radius of the epicycle, and also between the velocity of the planet in the epicycle and the velocity of the centre of the epicycle on the deferent, he was enabled to represent with considerable accuracy the apparent motions of the planets, and particularly their stations and retrogradations. As a first step towards connecting the sciences of astronomy and geometry the hypothesis of epicycles does great honor to its inventors.

Epicy'cloid [etymology same as for EPICYCLE], a curve traced by a point on the circumference of a circle which rolls on the convex side of a given fixed circle. It belongs to the class of curves called roulettes, and is not invariably a transcendental curve. It is always of a finite order when the circumferences of the two circles are commensurable. The normal of the epicycloid is easily constructed; it always coincides with the line which joins the generating point to the corresponding point of contact of the two circles. The evolute of the epicycloid is a similar epicycloid, the radii of the circles being merely altered in a certain ratio. When the circles are equal the epicycloid is similar, and similarly placed to the pedal of the fixed circle with respect to a point in the circumference. The curve is the cardioid, which is the inverse of a parabola. The epicycloid was invented by Romer, the Danish astronomer, who about 1674 proposed this curve as the best form for the teeth of wheels, in order to prevent friction. Newton gave its rectification in his "Principia."

Epidamnus. See DURAZZO.

Epidau'rus [Gr. Ἐπίδαυρος], an ancient town of Greece, on the E. coast of the Peloponnesus and on the Saronic Gulf, about 45 miles S. W. of Athens. It was an independent state, and possessed a small territory called *Epidauria*. As early as 600 B. C. it was one of the chief commercial cities of the Peloponnesus. It derived much importance from its temple of Æsculapius (situated 5 miles from the town), which was one of the most celebrated sanctuaries in Greece, and was frequented by patients from all of the Hellenic states. They came to be cured of their diseases. Here are the ruins of a magnificent theatre, which Mr. Leake says is in better preservation than any other in Greece. It is 370 feet in diameter. Once in four years a festival was celebrated here in honor of Æsculapius, with musical and gymnastic games. On or near the site of Epidaurus is a small village called *Epidavro*, at which the Greek congress assembled in 1821.

Epidau'rus Lime'ra, an ancient seaport-town of Greece, on the eastern coast of Laconia. In the Middle Ages it was the most important Greek town in the Morea. The ruins of its temples are visible at *Old Monemvasia*, 3 miles N. of Monemvasia.

Epidem'ic [from the Gr. ἐπί, "upon," and δῆμος, a "people"]. A disease is said to be epidemic when it attacks a considerable number of people, spreading rapidly throughout a community for a time, but not becoming permanent and *endemic* (*i. e.* not remaining as a disease characteristic of that particular community). Few subjects connected with medicine have given rise to more speculation than the cause and progress of epidemics. It appears certain that there must be either distempered conditions influencing the people who are subject to an epidemic, and predisposing them to the reception of disease-poisons, or else, what is more probable, that some peculiar disease-germs are present in air, water, or food during epidemics. Contagious epidemics, such as smallpox, measles, etc., are demonstrably propagated in this way. Others, like influenza and cholera, will propagate themselves in spite of personal quarantines, *cordons militaires*, and even of intervening oceans, though they may be intensified by near association with the sick. Some observers ascribe certain epidemics to the excess or deficiency of ozone in the air.

The germ-theory, which ascribes disease to microscopic vegetation, is a favorite with many; and some observers believe that they have detected the cause of various epidemics. For example, the cause of measles has been ascribed with confidence to the presence in the air of the spores of an organism identical with the rust of barley straw. Further observations will quickly establish or overthrow all such theories.

Mental epidemics, such as the dancing mania, lycanthropy, witchcraft, and the mania for suicide, are not improbably owing to physical conditions, like other epidemics.

The following laws or general statements with regard to epidemics appear to be established: (1) An "epidemic influence" appears at times to intensify disease, and immensely to stimulate the propagation of endemic diseases, thus converting them into epidemics. Thus, smallpox, typhus, typhoid, and scarlatina, usually endemic, sometimes rage with great violence as epidemics. (2) Sometimes an epidemic influence shows itself in the character of non-epidemic diseases. Thus, in some seasons pneumonia is of an active, sthenic type; at other times it almost uniformly assumes a low or typhoid character. In some seasons nearly all inflammations take on an erysipelatous form. (3) When a decided epidemic prevails, non-epidemic disease is very apt to show some of the features of the prevailing epidemic. Even before the advent of an epidemic these features may be observed. (4) The first onset of an epidemic is usually, not always, its most severe and fatal stage, but many such diseases have periods of exacerbation and of intermission. (5) Epidemics would appear to alternate in successive cycles, smallpox being followed, for example, by measles, scarlatina, or typhoid. (6) Some diseases occur both as epidemics and as sporadic diseases. In the former case the disease usually exhibits a greater tendency to depression and a larger proportionate mortality. (7) The lower animals to some extent share with man in special epidemic influences.

Facts are not wanting which give reason to hope that epidemics will become limited in their ravages. The plague and other destructive epidemics have become localized or endemic; and the introduction of thorough sewerage in cities, underground drainage in the country, habits of personal cleanliness, and other hygienic conditions cannot fail to accomplish much good. CHARLES W. GREENE.

Epiden'drum [from the Gr. *ἐπί*, "upon," and *δένδρον*, a "tree"], a large Linnæan genus of epiphytic orchids, which, as originally constituted, included the vanilla and many other species now excluded. It is worthy of mention as affording within the limits of the U. S. two examples of the tree orchids or epiphytes so abundant in the tropics. The *Epidendrum conopseum* grows principally upon magnolia trees, and is found in South Carolina, Georgia, and Florida. *Epidendrum venosum* grows in Florida. The blossoms, although rather pretty, are not conspicuous. Some of the tropical species are showy.

Epider'mis [from the Gr. *ἐπί*, "on," and *δέρμα*, "skin"], called also **Cu'ticle** or **Scarf-skin,** in anatomy, is in structure a modification of the epithelium, accurately moulded to the papillary layer of the true skin or derma. When exposed to pressure and friction it becomes hard and thick, as in the palms of the hands; otherwise it is soft. It is composed of agglutinated, flattened cells, but in the deep layers the cells are rounded or columnar, and filled with soft contents. In most races of men these deep cells contain more or less pigmentary matter, which gives the skin its various shades from black to white. The epidermis is penetrated by the ducts of the sweat-glands and oil-glands of the skin. Its cells are developed in the liquor sanguinis, which is poured out on the external surface of the true skin. The hair and nails in man, and also the horns in lower animals, are modifications of the epidermis.

The epidermis in plants is a layer of thick-walled cells, of character varying extremely in different species. It is entirely homologous in structure with animal epidermis. Upon leaves it is penetrated by the stomata, and both transmits exhalations and absorbs carbonic acid, the most important part of the plant's food.

Ep'idote [from the Gr. *ἐπί*, "upon" (implying "addition"), and *δίδωμι*, to "give," so named, it is said, because the series of the secondary forms are an enlargement on the base of the primary], a mineral which consists essentially of silica and alumina, combined with portions of lime, oxide of iron, or peroxide of manganese. A variety containing lime is called *zoisite*, and another containing manganese is termed *pistacite*. It is often found crystallized in prisms, and sometimes occurs massive. The color is generally green, yellow, or red.

Epido'tes [Gr. Ἐπιδώτης, the "liberal giver"], a Greek divinity worshipped at Lacedæmon. Of his mythus little is known. Also, the god of sleep, worshipped at Sicyon. The name was also a title of Zeus and other beneficent deities.

Epigæ'a [from the Gr. *ἐπί*, "on," and *γῆ*, "earth," "ground"], the name of a genus of plants. (See next article.)

Epigæ'a re'pens, the botanical name of the trailing arbutus or mayflower, an early spring flower of the U. S., well known for its beauty and fragrance. It belongs to the Ericaceæ, and in the Southern States is called ground laurel. It has decided diuretic powers.

Epiglot'tis [from the Gr. *ἐπί*, "upon," and *γλωττίς*, the "glottis," a name suggested by its position], the thin fibro-cartilaginous lid of the glottis. It is attached in front to the thyroid cartilage by two ligaments constituting a narrow neck. During respiration the epiglottis is vertical, and in the act of swallowing it automatically falls backward and closes the larnyx, thus preventing the passage of food into that organ.

Epig'oni [Gr. Ἐπίγονοι (from *ἐπί*, "on" or "after," and *γένω*, to "be born"); Fr. *Épigones*], a term signifying "successors" or "heirs," was a collective appellation of the sons of the seven Greek chiefs who conducted the expedition against Thebes. Their names were Alcmaeon, Thersander, Diomedes, Ægialeus, Promachus, Euryalus, and Sthenelus. They renewed the war and took Thebes. In the history of literature the name is sometimes applied to those writers who confine themselves to the further development of the ideas of the great masters of the classic period.

Ep'igram [Gr. *ἐπίγραμμα*, from *ἐπί*, "on," and *γράφω*, to "write;" Fr. *épigramme*], originally an "inscription" or brief writing; a short poem or piece of verse which has only one subject, and ends with a witty or ingenious turn of thought; an interesting idea expressed happily in a few words. The first of these definitions is nearly correct for a modern epigram, but differs widely from the original sense of the word in Greek. The Greek epigram was at first a short collection of lines inscribed on a monument or statue, and the word was afterwards transferred to short poems suitable for inscriptions. The general characteristics of Greek epigrams are perfect simplicity and the seemingly studied absence of that *point* which characterizes the modern epigram. But perhaps this seeming pointlessness is due to our ignorance of the circumstances under which they were written and to which they allude. It appears that the first and indispensable requirement of an epigram is not brevity nor sharpness, but *antithesis*. Epigrams are nearly all in one form of metre, the elegiac. Some of the epigrams of Catullus and Martial present the modern epigrammatic character; and Martial has in fact afforded the model on which the modern epigram has been framed. The French writers have been more successful in epigrams than any other modern writers, and they excel especially in those which are intended to be satirical and *piquant*.

Epig'ynous [from the Gr. *ἐπί*, "upon," and *γυνή*, a "female"], a botanical term applied to stamens and petals which grow on the summit of the ovary. These sometimes appear to be inserted on the ovary, in consequence of the coherence of the calyx with the ovary.

Ep'ilepsy [Lat. *epilep'sia;* Gr. *ἐπιληψία*, from *ἐπί*, "upon," and *λαμβάνω*, to "take," to "seize"], a disease of the nervous system, in which there are occasional seizures or fits of sudden and complete loss of consciousness, usually associated with convulsions, which become clonic, and finally impede respiration. The attack may last from two to twenty minutes, and is followed by exhaustion and sleep. In other cases, called *petit mal* (Fr. for "little sickness"), the loss of consciousness is but momentary, and there is no convulsion or falling down, as in ordinary attacks.

It has been customary to say that this disease is merely functional, because in most cases there is little or no apparent organic change of the brain observable after death; but the present opinion of pathologists appears to be that sufficiently careful observation will detect lesions, however minute, sufficient to account for the symptoms. Dilatation of blood-vessels in the medulla oblongata is frequently observed. The disease itself is of a frightful character, apart from the unhappy effects it may produce upon the mind of the patient.

When occurring in childhood, and especially during the period of dentition, it may after a time be spontaneously cured. It is sometimes hereditary, and often is caused by various excesses, by blows on the head, or by excessive fright.

The treatment during the paroxysm, if it be habitual, is simply to place the patient where he cannot hurt himself, to loosen his clothing, and give him plenty of fresh air. Between the paroxysms the patient should avoid all excesses of eating, of drinking, or of any other kind. Systematic exercise, and even gymnastics, never carried so far as to produce much weariness, are often beneficial. Nutritious food, with avoidance of coffee, tobacco, and stimulants, is usually advisable. A seton in the back of the neck is frequently useful. Of medicines, the bromides of potassium and of ammonium are useful in warding off the attacks, but they have little curative influence. Indeed, in the adult patient there is usually but little prospect of cure, though perfect recovery is not unknown. Tonics, such as iron, arsenic, and quinia, are useful in special cases, but in others are apparently worse than useless.

Notwithstanding the terrible effects of this disease upon the minds of many of its victims, not a few distinguished men have been epileptics, as were Cambyses, Cæsar, Mohammed, Petrarch, Henry IV. of England, Napoleon, and Byron. The ancients, it is said, sometimes called this disease *morbus basilicus* ("kings' disease"), from the idea that great men were especially liable to it; and among its numerous names was *morbus sacer* (the "sacred disease"), because the gods were believed to have especial care over its victims.

Epilo'bium [barbarously derived from the Gr. *ἐπί* λοβοῦ ἴον, a "violet on a pod"], or **Willow Herb,** a genus of herbaceous perennial plants of the natural order Onagraceæ, natives of temperate and cold climates. They have eight stamens and four petals. The fruit is an elongated many-seeded pod or capsule. Some of the species bear beautiful flowers. The *Epilobium angustifolium*, a native of Europe and of the U. S., has showy pink-purple flowers, and is sometimes planted in gardens. Several other species are indigenous in the U. S. The popular name willow herb was given in reference to the leaves, which resemble those of a willow. These leaves have astringent properties, and are reputed to have other active powers.

Ep'ilogue [Gr. *ἐπίλογος*, from *ἐπί*, "upon" or "after," and *λόγος*; Lat. *epilogus*], in dramatic poetry, the closing address to the audience at the end of a play. It was usually spoken by one of the actors, and was cheerful and familiar in tone. The term was sometimes applied to the conclusion of an oration.

Epim'achus, a genus of tenuirostral birds inhabiting Australia and Papua, and formerly classed with the birds

Epimachus Magnus, or Grand Plume-Bird.

of paradise. The *Epimachus albus* is of a fine violet-black color, with a broad collar of feathers, margined with green, at the base of the neck. Floating plumes, very long, white and silky, arise from the back and rump. Twelve of the lowest of these end in long thread-like points; hence it has been called the "twelve-threaded bird of paradise." The grand plume-bird (*Epimachus magnus*) is found in Papua. Its body is one foot long, its tail three feet. Its color is black-brown, the side-feathers curled and raised upward, glittering with changeable blue and green tints. The head and belly are of a lustrous blue. It is one of the most beautiful of all known birds.

Epimen'ides [Gr. Επιμενίδης; Fr. *Épiménide*], a famous Greek poet and prophet, was a native of Crete, and flourished about 600 B. C. According to tradition, he fell asleep in a cave, and awaked after the lapse of more than fifty years with a large increase of wisdom and inspiration. He wrote a poem on the voyage of the Argonauts. At the request of the Athenians, who were afflicted with the plague, he visited Athens about 596 B. C. and purified that city. Goethe wrote a poem called "Des Epimenides Erwachen."

Epime'theus [Gr. Επιμηθεύς; Fr. *Épiméthée*], a personage of the Greek mythology, was said to be a brother of Prometheus and the husband of Pandora. His name (from ἐπί, "on" or "after," and μῆδος, "consideration," "thought") signifies "afterthought."

Épinal, à'pe'nâl', a handsome town of France, capital of the department of Vosges, is pleasantly situated at the western base of the Vosges Mountains, on both sides of the Moselle, about 200 miles E. S. E. of Paris. It has a ruined castle, a fine Gothic church, a theatre, a hospital, a public library, and a museum of pictures and antiquities. Here are manufactures of cutlery, paper, hosiery, lace, chemicals, pottery, and linen fabrics. Pop. in 1866, 11,870.

Épinay, d' (Louise Florence Pétronille de la Live), Madame, a French literary lady, born about 1725. She was married at an early age to M. d'Épinay, but they were soon separated. She was intimate with Rousseau, for whom she built the hermitage at Montmorenci. Her work on education, entitled "Conversations of Emilie" (1783), gained a prize of the French Academy. Died in April, 1783. She left autobiographic memoirs (3 vols., 1818). (See Fallu, "La Marquise d'Épinay," 1866.)

Epiphania. See Hamah.

Epipha'nius [Gr. Επιφάνιος; Fr. *Épiphane*], Saint, a bishop and polemic, born at Eleutheropolis, in Palestine, about 310 A. D. He was educated in Egypt by certain monks, who instilled into his mind ascetic notions, and became afterwards a disciple of Hilarion. In 367 he became bishop of Constantia (formerly Salamis) in the island of Cyprus. He was an adversary of Origen, whom he denounced as a heretic, and he co-operated with those who deposed Chrysostom. He wrote, besides other works in Greek, a treatise against heresies, entitled "Panarium," which is one of the most important sources of information for the history of the ancient Christian Church. Best edition of his works by W. Dindorf (5 vols., 1859–63). (See Lipsius, "Zur Quellenkritik des Epiphanius," 1865.) Died in 402 A. D.

Epiph'any [Gr. Επιφάνεια, from ἐπί, "on," "over," "before," and φαίνομαι, to "appear;" Lat. *Epiphani'a;* Fr. *Épiphanie*], the name of a festival in the Christian Church, celebrated the twelfth day after Christmas (Jan. 6), to commemorate four events: (1) Christ's baptism; (2) his birth; (3) his manifestation to the magi; (4) the manifestation of his divinity in the miracle at Cana. Later, especially in the Western Church, it popularly commemorated the visit of the three wise men to the infant Jesus. The eve of Epiphany, called "Twelfth Night" in England and "Three Kings' Night" in Germany, was anciently a great popular festival. Its celebration is still kept up.

Epiphe'gus [from the Gr. ἐπί, "upon," and φηγός, a "beech tree," because it is found growing on the roots of that tree], a genus of herbs of the order Orobanchaceæ. Like all the order, it is a root-parasite, growing apparently from the ground, but really from the roots of trees. This genus is found only under beech trees; the herbs are purplish or yellow-brown, slender branched, with scales in place of leaves, and from six to twelve inches high. The *Epiphegus Virginiana*, common in the U. S., is called "cancer root," from the idea that it is curative of cancer.

Ep'iphyte [from the Gr. ἐπί, "upon," and φυτόν, a "plant"], the name applied to those plants which attach themselves to the bark of trees, and derive their nourishment chiefly from the air, whence the popular name of air-plant. These plants are found generally in tropical countries, and prefer moist and shady situations. The orchideous epiphytes have recently been cultivated with great success in green-houses. Many of them are of exquisite beauty, and others are remarkable for their singular and grotesque forms.

Epi'rus, or Epei'rus [Gr. Ἤπειρος; Fr. *Épire*], a country of ancient Greece, bounded on the E. by the chain of Pindus, on the S. by the Ambracian Gulf, and on the W. by the Ionian Sea. It corresponds to the southern portion of the modern Albania, a wild and mountainous region which in all ages has been occupied by semi-civilized and robber tribes, called *Epirots* or *Épirotes*. It is adapted to pastoral pursuits, and its fine horses, oxen, and Molossian dogs were celebrated in antiquity. The three most important tribes of Epirots were the Chaones, Molossi, and Thesproti. The Molossi eventually became the masters of all Epirus. Among the Molossian kings was Alexander, whose sister Olympias was married to Philip of Macedon. The most celebrated king of Epirus was Pyrrhus, under whose reign this kingdom attained its greatest power and splendor. He waged war against the Romans in Italy. Died in 272 B. C. Epirus became a Roman province in 168 B. C., and was conquered by the Turks in 1466. The chief towns of Epirus were Ambracia, Buthrotum, and Dodona. This region is still frequently called Epirus or "the Epirus." (See Merleker, "Das Land und die Bewohner von Epirus," 1841.)

Episcopal Church, The Protestant, the religious body formerly known as "the Church of England in America." The full official title of this communion is "The Protestant Episcopal Church in the United States of America," a name assumed, it has been surmised, to distinguish it from those Christians, on the one hand, who acknowledge the papal supremacy, and from those, on the other, who reject the authority of bishops. Whether this were really intended or not is perhaps doubtful; the name, however, describes with sufficient accuracy the relations of this Church to the other religious bodies in the United States.

The Episcopal Church is the descendant and representative of that branch of the Church of England which was

established in the North American colonies in the seventeenth century. The English adventurers of that and the preceding age, like the Spaniards and Portuguese, carried their national religion with them, and introduced it wherever they gained a footing. The instructions given to Sir Humphrey Gilbert in 1578 gave him authority to settle in any country which was not in the possession of any Christian prince. He was to govern his colonies by laws agreeable to the policy of England, and not against the Christian faith professed in the Church of England. This expedition terminated, indeed, in disaster and in the death of the commander; but similar principles guided the expedition which set sail for the "western parts of America" in 1607, under the command of Captain Newport, of which the Rev. Robert Hunt, a man of energy and ability in civil affairs, as well as a learned and devout divine, was the chaplain. Under his guidance and supervision the foundations of the Church in Virginia were laid; and although it doubtless suffered from his early death, it gradually increased in strength and influence, and became the established religion of that colony. In Maryland, and in what are now called the Middle States, the Church of England was introduced at an early date. In New England, where Puritanism had a predominating influence, churchmen were longer in gaining a footing, which, when gained, they were obliged to make good against determined opposition.

Without tracing the history of the Church through the colonial period, it may be sufficient to say that, notwithstanding many drawbacks, it had in the year 1776 gained a very respectable position. It had been all along, however, obliged to contend not only with open enemies, but with injudicious friends. The violent measures of Andros and others had tended in some places to increase the dislike to the English Church which was felt by the Puritans of New England and New York, and by the numerous sectaries who, attracted by Lord Baltimore's proclamation of a general toleration, had swarmed into Maryland. The attempts which were made from time to time to procure bishops for America had failed, principally from political causes, and the Church, thus deprived of the presence of the highest order of its ministry, was necessarily crippled in the performance of its functions. The want of bishops threw difficulties in the way of raising up a native ministry. Young men who sought holy orders were obliged to make a long and perilous voyage to England to be ordained, and they were fortunate if they returned in safety. The smallpox in the eighteenth century was the peculiar scourge of the colonists who visited England; and this disease, justly dreaded in those days, carried off many of the most promising youths of America. The devotion of colonial churchmen, however, to their religion continued firm and unwavering; and although they encountered further trials at the time of the Revolution, they were able not merely to overcome them, but to place their Church in a position which has enabled it ever since to increase in influence and members.

At the beginning of the Revolutionary war there were in the Middle and Eastern States about eighty parochial clergymen. These gentlemen, with the exception of those in the great cities, were for the most part dependent for their support upon the Society for the Propagation of the Gospel. This society, however, withdrew its gifts after the termination of the war. In other respects, also, the conclusion of peace left the Church in a depressed condition. Many of the clergy and laity had adhered to the Crown during the struggle, and at its close withdrew themselves to England or to the colonies which continued loyal. The peace was soon followed by the confiscation of the landed endowments of the Church in Virginia, and the numerous churchmen in that State were thrown upon their own resources. The Church was poor, and its prospects were not hopeful.

Two important measures were immediately necessary—to obtain an episcopate, and to promote a closer union between the churches in the several States. The first was necessary to the existence, the second to the well-being, of the Church. Under the old Confederation the States regarded themselves as independent sovereignties, and by consequence the churches in them conceived themselves to be so many national churches. This position, if it had continued, would not indeed have affected their faith and doctrine, which are unchangeable, but it might nevertheless have produced many inconveniences. By the principles of the Church of England, every national church, while it is bound to adhere to the common faith of Christendom as a heritage from the apostles, has a wide liberty in regulating its own ceremonial, discipline, and worship. Thus, the Prayer-Book might have been altered in a different way in different States, and divergences in discipline and government might have been developed to such an extent as to make the relations between the churches an alliance rather than a union. This danger was averted, almost by an accident. A few clergymen from New York, New Jersey, and Pennsylvania met at New Brunswick, in New Jersey, to take measures for reviving an old society (which still exists) for the support of the widows and children of the clergy. They naturally discussed the condition of the Church, and made arrangements for a larger meeting to be held soon afterwards in New York, to which representatives of the laity were to be invited. This meeting, however, did little more than lay down certain general principles—with reference particularly to episcopacy and the Common Prayer-Book, which they rightly conceived would tend to promote a real union between the churches in the several States—and issue a call for a similar meeting to be held the next year in Philadelphia. This was the beginning of the General Convention, which has ever since been regarded as the governing body of the Church in the United States.

The constitution of this body, as it was soon afterwards established, required it to consist of all the bishops, and of four clergymen and as many laymen from each State. By later amendments, when more than one bishop was placed in a State, every diocese or episcopal jurisdiction became entitled to a representation of four clerical and four lay deputies, and the lay deputies were required to be communicants. All the bishops were entitled to seats *ex officio;* and it was arranged that as soon as there should be three or more they should sit in a separate house. Every act was to receive the approbation of both houses. Authority was given to the General Convention to prescribe the qualifications for ordination and to set forth a Book of Common Prayer—the two things that were most necessary for establishing such a union as was desired. It was also directed that there should be a convention in every State, consisting of clergy and laity, the powers of which were not in any way defined. It seems to have been assumed, however, that these conventions were to exercise supervision over the affairs of the Church in every State—or, to use the more recent expression, in every diocese—in all matters which did not come within the immediate jurisdiction of the bishop.

This constitution was adopted in the several States, though not immediately in all. The Convention of 1785 had consisted of delegates from what were afterwards called the Middle States, and from Maryland, Virginia, and South Carolina. Much doubt was felt in the East, particularly in Connecticut, as to the wisdom of some of its provisions. The introduction of the laity especially into what was conceived to be a Church council was regarded as an experiment of questionable expediency, and some of the powers which were given them were thought to be without precedent. These objections, however, were gradually removed or waived; and in 1789, Bishop Seabury, with a deputation from Connecticut, took his seat in the General Convention, and the union of the Episcopal churches in the United States was completed. Although the constitution proposed in 1785, and adopted in an amended and completed form in 1789, all along contemplated the presence of bishops, there really were none in the United States at that time except Bishop Seabury, who took no part in the proceedings of the Convention. This gentleman (the second of a family which for five generations has furnished a line of clergymen, all able and some distinguished) had been sent to England soon after the peace by the clergy of Connecticut to obtain consecration from the English bishops. He had found an obstacle, however, in the oath of allegiance, which forms a part of the English consecration office, and which, of course, could not be taken by any one but a British subject. After some delay, and much negotiation, he succeeded in obtaining consecration from the Scottish bishops, and, returning to America in 1785, was received as bishop of Connecticut and Rhode Island.

The rule of the Church, believed to have come down from the apostles themselves, requires the presence of at least three bishops at every consecration; and it was necessary that there should be at least that number in the United States to maintain an episcopal succession. Application was therefore made in 1786 to the English bishops in behalf of the Rev. William White and the Rev. Samuel Provoost, who had been chosen to the episcopate in Pennsylvania and New York. The obstacle arising from the oath of allegiance was removed by an act of Parliament; but a new difficulty was found in a revised Prayer-Book which had been proposed for use in the United States in 1785, and in which the English bishops thought that they perceived indications of a disposition to depart from the doctrine of the Church of England. After a correspondence between some of the most learned divines in England and the United States, in which the principle was clearly brought out that "this Church does not intend to depart from the Church of England in any essential point of doctrine, discipline, or wor-

ship, or further than local circumstances require," it was agreed to proceed with the consecration of these gentlemen, and they were accordingly consecrated bishops on the 4th of February, 1789, in the archbishop's chapel at Lambeth, by the Most Rev. John Moore, archbishop of Canterbury, assisted by other bishops. Partly because it was desirable that there should be more than the lowest number of bishops necessary to maintain a succession, and partly to keep up the succession in the English line, the Rev. James Madison obtained consecration in 1790 as bishop of Virginia.

The "Proposed Prayer-Book," as it was called, which had never met with much favor, was allowed to fall into oblivion, and it has now become one of the curiosities of ritual literature. A new revision of the Prayer-Book was made upon the principle just indicated. The English Prayer-Book was retained, with such alterations as were necessary to adapt it to the changes in the political condition of the country, and with many other (chiefly verbal) modifications. The promise, however, to adhere to the doctrine, discipline, and worship of the Church of England was, upon the whole, strictly adhered to. The most important changes were the introduction of a communion office closely resembling that of the Scottish Episcopal Church, and more nearly approaching the older liturgies of England, which was done at the request of Bishop Seabury and at the instance of the Scottish bishops; the omission of the Athanasian Creed; and the leaving out the precise directions about confession which occur in the English Office for the Visitation of the Sick. This omission was perhaps balanced, and the mind of the Church sufficiently declared, by the stringent rules about confession which are found in the Office for the Visitation of Prisoners, borrowed from the Irish Prayer-Book. The Prayer-Book, thus revised, was ratified in 1789. It came into immediate and general use, and has ever since been, without material alteration, the "use of the Protestant Episcopal Church in the United States."

The two objects which the Convention had in view in 1785 were thus attained in 1789. There was a sufficient number of bishops, and the union of the Church in the United States was perfected. Since that time a hundred bishops have been consecrated, of whom fifty-one are living. There are nearly 3000 priests and deacons, and the number of communicants is computed at 235,000. The Church has extended into every State and Territory, and its missionaries have penetrated into Western Africa, China, and Japan. In the General Convention of 1789 (that in which the union of the Church was perfected) two bishops sat with twenty-nine clerical and lay deputies. That of 1871 consisted of forty-two bishops and three hundred and twelve clergymen and laymen. The number of churches and chapels is estimated at about 2700. There is a general theological seminary in the city of New York, and there are divinity schools in Connecticut, Ohio, Pennsylvania, Massachusetts, Wisconsin, and Minnesota. Several colleges are connected with this Church, among which are Trinity College, Hartford, Hobart College, Geneva, Racine College and Burlington College, in the States of Connecticut, New York, Wisconsin, and New Jersey. The University of the South was begun a few years ago with some prospects of success, but the events of the war delayed its progress, and its usefulness will probably be rather in the future than in the present. Faculties of divinity and grammar-schools are attached to several of the colleges. St. Stephen's College, Annandale, N. Y., receives at an early age youths who are designed for holy orders, and carries them to the point at which they begin their theological training. Trinity School, N. Y., an endowed grammar-school established in 1706, receives seventy-two boys on the foundation.

The doctrine of the Episcopal Church is that of the Church of England, believed to have been the common faith of Christendom while it continued undivided. The relations of this Church to the rest of Christendom were clearly defined by the bishops who met in conference at Lambeth in 1867. More than seventy bishops from England, Scotland, Ireland, the colonies, and the United States met in that year to take into consideration the state and best interests of the churches of the Anglican communion. One of their first acts was to express the deep sorrow with which they viewed "the divided condition of the flock of Christ throughout the world," and to record their conviction that "unity will be most effectually promoted by maintaining the faith in its purity and integrity, as taught in the Holy Scriptures, held by the primitive Church, summed up by the creeds, and affirmed by the undisputed general councils; and by drawing each of us closer to our common Lord, by giving ourselves to much prayer and intercession, by the cultivation of a spirit of charity and a love of the Lord's appearing."

The Episcopal Church, while it receives the Holy Scriptures as the ultimate rule of faith, does not throw them open to the varying interpretations of every man's private judgment, but explains them by the aid of traditions which it believes to have come down through an unbroken line of teachers from the apostles themselves, by the creeds, and by the definitions of Christian doctrine made by the general councils. Candidates for baptism are required to confess their faith in the words of the Apostles' Creed—adults in person, and infants by their sponsors. Communicants must receive also the Nicene Creed, which contains the same teachings in a more expanded form. Nothing is required from laymen, beyond acceptance of the Prayer-Book and a proper deference to the instructions of the clergy, who are believed to derive their doctrine and their right to teach by a succession from the apostles. The XXXIX. Articles of the Church of England (except the twenty-first, "of the power of Christian princes in relation to general councils") are still commonly bound up with the Prayer-Book, but the practice of signing them has been laid aside since the Revolution. The clergy sign, instead, a general declaration that they "believe the Holy Scriptures of the Old and New Testament to be the Word of God, and to contain all things necessary to salvation;" and they "solemnly engage to conform to the doctrines and worship of the Protestant Episcopal Church in the United States." The mode in which the teachings of Holy Scripture are ascertained has been already pointed out.

Thus, the Episcopal Church would seem to be one of the most liberal and comprehensive of religious bodies. It *may* contain within itself (it is not, however, asserted that it *does*) those, on the one hand, who apparently differ from Roman Catholics in little more than in denying the pope's jurisdiction in countries which are or have been included in the British empire, and, on the other, those who are to be distinguished from Presbyterians only by their acceptance of episcopacy and the Prayer-Book. Within these possible limits there would appear to be ample scope for religious thought; and the great freedom of religious thought accounts for the schools of teaching which have long existed. As men incline toward authority on the one hand, or individual judgment on the other, they are said to be High Church or Low Church. The lines of thought, however, are not sharply drawn, and the schools melt into each other by imperceptible degrees. The principles laid down by the Fathers at Lambeth (themselves men of every conceivable school of thought) have been long tested, and have been found sufficient to maintain the unity and harmony of the Church.

BEVERLEY R. BETTS, *Lib. of Columbia Coll.*

Episcopal System, in the Roman Catholic Church, is that theory according to which the highest clerical power is vested in the whole body of bishops. This theory was most prominently brought forward in the papal elections of the fourteenth century, and its followers declared the Church, as represented in its general assemblies, to be above the pope. In France the University of Paris was the chief supporter of this theory, and the Gallican Church accepted it as one of its fundamental laws. In Germany the coadjutant bishop of Treves, Nikolaus von Hontheim, who was one of its chief supporters, wrote a celebrated book, in which he clearly defined the episcopal system, "De statu ecclesiæ et legitima potestate Romani Pontificis" (1763). The Punctations of Ems (see EMS) had the same fundamental idea, and although they failed in their purpose, the system continued to spread in Germany. But the declaration of papal infallibility has put an end to these differences, and made an impossibility of the episcopal system. In the German Protestant churches the episcopal system is that theory according to which the authority of the bishops, which had been suspended in the Protestant countries in consequence of the peace of 1555, was transferred to the ruler of the country.

Episco'pius (SIMON), a learned Dutch divine whose original name was BISSCHOP, was born in Amsterdam in Jan., 1583. He was distinguished for his liberality, moderation, and other virtues, and became the chief pillar and champion of the Arminians or Remonstrants. He was appointed professor of theology in the University of Leyden in 1612, but he was accused of Socinianism by the Calvinists (Gomarists), and was banished in 1618 by the Synod of Dort. He retired to France, returned to Holland in 1626, and became rector of a college in Amsterdam in 1634. His principal works are the "Confession of the Remonstrants" (1621) and "Institutiones Theologicæ." Died in 1643.

Ep'isode [Gr. ἐπεισόδιον, from ἐπί, "on," "in addition to," εἰς, "in" or "into," and ὁδός, a "road," a "journey," a "coming;" *i. e.* something that comes in besides the main plot or poem] was originally one of those parts of an ancient classical drama which were performed between the entrances of the chorus. In modern use it signifies an incidental narrative or digression in a poem, more or less connected with the main plot, but not essential to its development.

Epis'tates [Gr. *ἐπιστάτης*, from *ἐπί*, "on" or "over," and *ἵσταμαι*, to "be placed," to "stand"], literally, "one set or placed over," the title of the presidents of the two great councils of the ancient Athenians—viz., the Ecclesia and the senate of Five Hundred. Their term of office was one day.

Epis'tle [Lat. *epis'tola;* Gr. *ἐπιστολή*, from *ἐπιστέλλω*, to "send"], literally, a thing *sent*, hence a letter. The name is now given especially to the twenty-one epistles of the New Testament. The writings ascribed to the so-called Apostolic Fathers (Clement of Rome, Barnabas, Ignatius, Polycarp, and Hermas) are for the most part epistolary in form. Of quite inferior dignity and value are the following undoubtedly spurious epistles: Abgarus of Edessa to Christ, and Christ to Abgarus; Lentulus to the Roman Senate; several of the Virgin Mary; Paul to the Laodiceans; the Third of Paul to the Corinthians, and one of the Corinthians to Paul; Peter to James; eight of Seneca the philosopher to Paul, and six of Paul to Seneca.

Epis'tolæ Obscuro'rum Viro'rum [Lat. for "letters of obscure men"], a famous collection of satirical letters directed against the monks and the Roman Catholic Church. They were published in three parts—the first at Haguenau (1515), the second at Bâle (1517), and a third at a later date. They were probably written jointly by Ulrich von Hutten, Crotus Rubianus, and Buschius. They are an admirable imitation of the barbarous Latinity of the monks of those days. Certain Dominicans at Cologne, under the lead of one Pfefferkorn, a baptized Jew, advocated the expulsion of all Jews from Germany, the forcible education of their children in Christian doctrine, and the burning of their books. This attempt was opposed by Reuchlin; and pending the decision of the question by the pope the "Epistolæ" appeared. Says Sir William Hamilton: "The 'Epistolæ' are at once the most cruel and most natural of satires, and as such they were the most effective. They converted the tragedy of Reuchlin's persecution into a farce; annihilated, in public estimation, the enemies of intellectual improvement; and even the friends of Luther, in Luther's lifetime, acknowledged that no other writings had contributed so powerfully to the downfall of the papal domination." Many editions of the "Epistolæ" have been published, the best of which is that of Boecking, Leipsic, 1858.

Ep'itaph [Lat. *epita'phium*, from the Gr. *ἐπί*, "upon," and *τάφος*, a "tomb"] was anciently the name of the monument or tomb over a grave, and was especially applied to the funeral oration delivered at the grave. It is, however, universally applied at present to the inscriptions upon tombstones. The literature of epitaphs is very considerable. Greek epitaphs are preserved in great numbers in the Anthology. Of Latin epitaphs, many exist both in literature and upon the tombs themselves. Numerous interesting examples of early Christian epitaphs have been taken from the Catacombs. Many collections of remarkable epitaphs in modern languages have also been made.

Epithala'mium [from the Gr. *ἐπί*, "on" or "near," and *θάλαμος*, a "bridal chamber;" also "marriage"], a bridal hymn; a chorus sung, in ancient Greece, near the door of the bridal chamber. It appears to have been a formal part of the marriage ceremony. Among the ancient Romans the rude Fescennine songs, which seem to have been of a phallic character, were often sung at weddings, and are hence called epithalamia. The term is often given to formal poems composed in honor of a particular marriage. Anacreon and Pindar composed poems of this kind. The most perfect example of it now extant is the epithalamium of Peleus and Thetis, by Catullus.

Epithelio'ma [from EPITHELIUM, which see], a variety of cancer which attacks most frequently the surfaces which are covered with pavement epithelium or with epidermis. Many pathologists class it with "cancroid" disease, because it appears to be less malignant than true cancer. Indeed, if removed early, the patient has a fair prospect of future exemption from the disease, but in neglected cases it assumes the malignancy and other dreadful characters of true cancer. The lips, especially the upper lip, are the most frequent seat of epithelioma, but it may attack even internal organs. Histologically, it appears to be composed of epithelial elements.

Epithe'lium [from the Gr. *ἐπί*, "on," and *θῆλυς*, "soft," "delicate," "tender," because used to protect the delicate tissues beneath], in anatomy, is the layer of cells which lines the serous (or closed) and the mucous (or open) cavities of the body, the mucous epithelium being continuous with the epidermis, which is a modification of the epithelium.

Epithelium is of two principal kinds: (1) "Pavement" epithelium, consisting of rounded or polygonal cells. This variety is especially found in the closed cavities, but is not confined to them. (2) "Columnar" or cylinder epithelium, found chiefly upon mucous membrane. This kind has many varieties of form, one of the most important being "ciliated epithelium," which is provided with fine hair-like processes (cilia), whose length varies from one one-thousandth to one twelve-thousandth of an inch. These cilia have a rapid automatic motion in one direction, moving from 150 to 250 times in a minute. These motions are no doubt highly important in physiology, but their mechanism is little understood. In some instances these motions obviously assist in discharging excretions, etc., but in others their use is quite unknown. The epithelial cells have a very important part in the secretion of many fluids. For example, mucus is formed by the bursting of epithelial cells and the discharge of their soft contents, mingled with the débris of the old cell-walls. This process of destruction is attended by continual renewal of the cells.

Ep'ithet [from *ἐπί*, and *τίθημι*, to "put upon"], a word or clause which expresses some attribute of an object that is prominent in thought, but is not made the basis of a discrimination or classification; *e. g.* "*Frail* man is mortal;" "Earthly pleasures, *which are fleeting and unsubstantial*, are not the highest for man." Used in opposition to DEFINITIVE (from *de* and *finio*, to "mark out the *fines* or boundaries"), by which we understand a word or clause which expresses some attribute that *is* made the basis of a discrimination or classification; *e. g.* "*Good* men [*i. e.* only good men] are a blessing to the community;" "Those pleasures *that are from the earth* are not the highest for man."

Great care should be taken that epithets be not too frequently employed, and that there be something in the thought to which they actually and exactly correspond. The felicitous employment of epithets is one of the attributes of genius which gives to literature its highest charm. See Milton's

"Drew *iron* tears down Pluto's cheek."

Epit'ome [Gr. *ἐπιτομή*, a "cutting short" (from *ἐπιτέμνω*, to "cut," to "gash," also to "abridge")], in literature, an abridgment; a work in which the contents of a former work are reduced into a smaller space by curtailment and condensation. In the declining age of the Western Roman empire the practice of epitomizing the works of older writers, especially in history, became very prevalent. In several instances a valuable original work has been lost which perhaps would have been preserved if an epitome had not been substituted for it. Among the best known works of this class are the epitome of Florus, "Epitome Rerum Romanarum," and that of Eutropius, "Breviarum Historiæ Romanæ," both abridgments of the history of Rome.

Epitro'choid [from the Gr. *ἐπί*, "on," and *τρόχος*, a "wheel"] is a curve traced by a point in the plane of a circle which rolls on the convex side of a fixed circle. The curve thus generated is one of the family of roulettes, and becomes an epicycloid when the generating point is in the circumference of the rolling circle. When the two circles are equal the epitrochoid becomes similar to the pedal of the fixed circle with respect to a certain fixed point in its plane. But the pedal being always the inverse of the reciprocal of the primitive curve, the epitrochoid in this case must be the inverse of a conic with respect to one of its foci, which latter is a curve of the fourth order, belonging to the Cartesian ovals, and called the *limaçon*. Epitrochoids are generally transcendental curves; it is only when the circumference of the fixed and rolling circles are commensurable that the epitrochoid returns into itself and becomes an algebraical curve.

Epizo'a [a Gr. term, from *ἐπί*, "on," and *ζῶον*, an "animal"], a name given to animals living upon the skin and among the hairs of other animals, as fleas, lice, ticks, mites, etc. Some of these, like the itch-mites, are Acarina—spiders of low grade of development—but most are insects of spider-like character, low forms of Diptera and Hemiptera. Most mammals, many birds, and a great many insects are infested by insect parasites. The *Cyamus ceti*, or whale-louse, living upon whales and fishes, is a crustacean. Many Cirripedia live in a similar way upon whales and sharks. Most Epizoa live as true parasites upon the blood and secretions of the animal which they infest. Others, especially the Cirripedia, appear to feed upon other food, making the skin of a larger animal merely their place of abode. The very great majority of Epizoa are articulate animals.

Epizoöt'ic [from the Gr. *ἐπί*, "upon," and *ζῶον*, an "animal"], a disease which attacks the lower animals, or any one species of them, as epidemics attack men. The term is objectionable, because, with some limitations, these diseases chiefly attack but one species, instead of all animals; and moreover, as man is an animal, all epidemics are epizootics. The so-called epizootic diseases follow the general laws of epidemics, and they would appear to attack especially the

domesticated animals. Some diseases attack both man and the lower animals. Thus, smallpox affects the horse, cow, and sheep, assuming in each a modified form. Among the more important epizootic diseases are the rinderpest, the contagious pleuro-pneumonia, and the "foot-and-mouth disease" (all attacking neat cattle): the remarkable influenza which attacked horses and mules, arising in Canada Sept. 30, 1872, and rapidly moving southward and westward over the whole of North America; the scab, foot-rot, and other diseases of sheep. The "reds," the *muscardine*, *pébrine*, and other diseases of the silkworm have been the cause of serious calamities to operatives, and at times have almost threatened the existence of the silk manufacture.

The epizootic influenza of 1872–73, above alluded to, destroyed, according to Dr. A. B. Judson of New York, 1500 horses and mules in New York, or 4 per cent. of the total number in the city. The disease reached Chicago Oct. 29, St. Louis Dec. 1, Salt Lake Jan. 11, 1873, and San Francisco April 15. It is thought that the disease spread chiefly by contagion, and not by atmospheric influence.

E Plu'ribus U'num [Lat.], "One composed of many," the motto of the U. S., consisting of many States confederated.—*Webster*. [Lat.], "One of many," the motto of the U. S.; the allusion being to the formation of one federal government out of several independent States.—*Worcester*.

After the Declaration of their independence by the States was announced on the 4th of July, 1776, and before the adjournment of that day's session, it was resolved, "That Dr. Franklin, Mr. J. Adams, and Mr. Jefferson be a committee to prepare a device for a seal for the United States of America." The result of their joint work was the present seal of the U. S., which has not been changed since its first adoption. The six sections, or quarterings, upon the escutcheon or shield were intended to denote the countries (England, Scotland, Ireland, France, Germany, and Holland) from which the States so united had been, respectively, chiefly peopled. The motto adopted on this seal, and which has ever since been retained, was intended to denote the character of the federal government in its formation, as stated by the great American lexicographers, Webster and Worcester, in their above definitions. From the six quarterings on the shield, with the necessary seven attending spaces outside of the sections or quarterings, arose the original thirteen stripes, as they are called, which were transferred to the flag of the Union in 1777. The stars were intended to represent the number of the States, while the origin of the stripes was the quarterings or sections of the shield, as stated. ALEXANDER H. STEPHENS.

Eppard's Point, a twp. of Livingston co., Ill. P. 861.

Ep'ping, a town of England, in Essex, is at the N. end of Epping Forest, 16 miles N. N. E. of London. It is noted for its cream, butter, and sausages. Epping Royal Forest, formerly Waltham Forest, covers 60,000 acres, but was once much more extensive. 12,000 acres are in woods and wastes, and the other part is enclosed. Pop. 5566.

Epping, a post-township of Rockingham co., N. H., on the Portsmouth R. R., 39 miles S. E. of Concord. It has four churches, and manufactures of shoes, brick, lumber, woollen goods, etc. Pop. 1270.

Epps, a township of Butler co., Mo. Pop. 263.

Ep'som, a market-town of England, county of Surrey, 14 miles by railway S. S. W. of London. It has a mineral spring containing sulphate of magnesia, which derives from this place the name of Epsom salt. Here is a royal medical college. Epsom is famous for its horse-races, which are held yearly on the Downs, 1½ miles S. of the town. The races last four days, one of which is called "Derby Day," and are more numerously attended than any other races in the kingdom. Pop. 4882.

Epsom, a post-township of Merrimack co., N. H. It has manufactures of lumber, etc. Pop. 993.

Ep'som Salt [Lat. *magnesiæ sulphas* (*i. e.* "sulphate of magnesia"); Ger. *Schwefelsaure Magnesia*], the magnesium sulphate (SO_4Mg7OH_2), a salt, when pure, usually found in colorless acicular crystals derived from the right rhombic prism, and containing 51.22 per cent. of water of crystallization. It is somewhat efflorescent, for at 32° Fahrenheit water will dissolve over one-fourth its weight of the anhydrous salt, and as the temperature is raised the solubility increases. The salt was formerly manufactured from the waters of the mineral spring of Epsom, England. It also exists largely in sea-water, from which it was formerly prepared in large quantities. In Italy it is now prepared from a schistose rock; in England, from dolomite; in Pennsylvania and Maryland, from magnesite. This salt is used in medicine as a cooling and generally safe cathartic. It is nauseous to the taste, but may be easily taken in "soda-water" with lemon syrup. In the household it is an excellent addition to starch, decidedly increasing its stiffening powers. Mixed with ordinary whitewash, it gives a fine pearly whiteness to walls.

Equal'ity, a post-village of Gallatin co., Ill. Pop. 356.

Equality, a township of Miller co., Mo. Pop. 1068.

Equa'tion [Lat. *æqua'tio*, *æqua're*, to "make equal"], in algebra and the calculus, an expression denoting that two quantities symbolically expressed are equal. The sign = placed between the two quantities equated denotes this relation. Either quantity may be expressed in a single term, or in more terms than one, connected by the sign + or −. The term or terms on the left of the sign of equality constitutes what is called the first member of the equation; the term or terms on the right, the second member. In analysis there occur equations of two classes, distinguished as *algebraic* and *transcendental*. Algebraic equations are those in which the quantities employed are subjected to no operations but the operations of common algebra, including addition, subtraction, multiplication, division, and involution to powers or evolution of roots, expressed by constant indices. Transcendental equations are those whereinto relations are introduced to which the ordinary operations of algebra are inadequate, as when the exponents of powers are variable, or when the trigonometrical functions of variable angles enter as terms or factors. Such relations are called transcendental (see TRANSCENDENTALS), and give name to the equations in which they occur. The object of algebraic equations is usually to ascertain the value of some unknown quantity through its relations to other quantities which are known. If there is but one unknown quantity, a single equation will suffice for the solution. If there are two or more, there must be as many equations expressing relations independent of each other as there are unknown quantities. If the number of independent equations is smaller than the number of unknown quantities, the problem to which they belong is indeterminate. It can then be made determinate by forming a sufficient number of independent equations with arbitrary conditions. If the number of independent equations is greater than the number of unknown quantities, the problem to which they are supposed to belong is impossible. In this case some of the conditions which these equations express are incompatible with each other; but if, after eliminating all the unknown quantities from them, we treat the constants which remain as if they were unknowns—that is, make them arbitrary constants—the resolution of the group with respect to these will show what relations they must have to each other, or the conditions which must exist, in order to render the original set of equations determinate. They are therefore called *equations of condition;* which term is generally applicable to all equations which express necessary relations between quantities, without any regard to their absolute value.

The equality between the members of an equation is not affected by subjecting both to the same operation. Thus, if both members be multiplied or divided by the same quantity, increased or diminished by the same quantity, raised to the same power, depressed to the same root, made the values of similar trigonometrical functions of the same angle, or taken as the exponents or logarithms of the same assumed constant or variable, under all these transformations the relation of equality between them is preserved. If any term be transposed from one member to the other of an equation, the equality is still maintained, provided the sign of the term transposed be changed from + to −, or from − to +, at the same time. If all the terms of one member be thus transposed to the other, this member is reduced to 0, but the equality is still preserved. In all general discussions of the theory of equations it is common to consider the equation under this form; *i. e.* with the significant terms on one side and *zero* on the other.

An *identical* equation is one in which precisely the same terms are found on one side as on the other, or in which this exact similarity is producible by performing operations on one side or the other, which change the form without altering the value. Thus,

$$\frac{cy^2 + cx^2 + 2axy + ay^2 + 2cxy + ax^2}{a + c} = (x + y)^2$$

is an identical equation, because, by properly arranging the terms of the first member, and actually performing the division by $a + c$, and by developing the second member at the same time, we have $x^2 + 2xy + y^2 = x^2 + 2xy + y^2$. An identical equation is obviously no help towards the solution of a problem.

The *degree* of an algebraic equation is denoted by the highest power of the unknown quantity contained in it, if it has but one, and by the greatest sum that can be found by adding together the exponents of all the unknowns which are factors in any single term, if there are several. An equation of the first degree is called a simple equation. If it has but one unknown, it is resolved by transposing

all the terms into which the unknown enters to the first member, and all those into which it does not enter to the second; then resolving the first member into two factors, of which one shall be the unknown; and, finally, dividing both members by the second factor of the first member—that is, by the coefficient of the unknown quantity. If a simple equation contains more than one unknown, then singly it is indeterminate. To be determinate there must be just as many equations (not transformable into each other) as there are unknowns. In this case, if we find from one of the equations the value of one of the unknown quantities in terms of the others (*i. e.* by treating all the other unknowns as knowns for the time being), and substitute the value so found in all the remaining equations, we shall have eliminated, or got rid of, one of the unknowns, and have made the number of equations one less at the same time. Following up this mode of proceeding, we shall at length have but one equation and one unknown quantity; of which last therefore the value is obtainable in known terms. The values of the rest are then easily deducible by successive substitutions.

Equations of the second degree can always be reduced to the form $x^2+2px=q$. For if originally there are many terms containing x^2 and x, and also many known quantities, all the unknowns having been brought to the first member and the knowns to the second, the term or group of terms containing x^2 may be resolved into two factors, of which one shall be x^2 itself, and the whole equation may then be divided by the other factor. Then all the knowns forming the coefficient of x may be represented by $2p$, and the entire second member may be represented by q. In this case it *may* happen that the coefficient of x is negative. If so, the *implicit* value of p is said to be negative, while its *explicit sign* is positive. This matter must be attended to when the values which p replaces are restored. The quadratic having the form above, its solution, which presents two values, either of them capable of satisfying the equation, is as follows:

$$x=-p+\sqrt{q+p^2},$$

$$x=-p-\sqrt{q+p^2}.$$

Any equation, whatever its degree, which contains but two powers of the unknown, is reducible precisely like a quadratic, provided that the indexes of the two powers are in the relation of 2 to 1. For, supposing the two powers to be m and n, we can always reduce the equation to the form $x^m+2px^n=q$, or $x^{2n}+2px^n=q$. Hence, from what has just been said it appears that $x=(-p\pm\sqrt{q+p^2})^{\frac{1}{n}}$.

For the manner of reducing cubic, biquadratic, and higher equations resort must be had to systematic treatises. The following are a few of the propositions of general interest in regard to the theory of equations which are admissible in an article having the necessarily limited scope of the present.

Every equation of whatever degree (say the m^{th}) is capable of being reduced to the form $x^m+Ax^{m-1}+Bx^{m-2}+Cx^{m-3}\ldots\ldots+Px+Q=0$; in which the coefficients A, B, C, etc. are positive or negative, whole or fractional, real or imaginary, as it may happen. If an equation has as many real roots as its degree indicates, the coefficient A will be the sum of all these roots with signs reversed. If the several roots are a, b, c, etc., the equation itself is the product of the binomial factors $x-a$, $x-b$, $x-c$, and so on; so that the constant (or known) term Q is the *product* of all the roots a, b, c, etc., with signs reversed. If there are not so many different real quantities which will satisfy the equation as the number of units in the exponent of the degree, then there will be *imaginary* roots (quantities containing an *even root of a negative* quantity), and these, when present, are always present in pairs, each member of a pair containing the same real and imaginary terms, the imaginary term with contrary signs. Such pairs of roots are called conjugate roots. If one of the real roots (as a) of an equation is known, the equation is divisible by the binomial $x-a$, and may thus be depressed in degree to the next lower order. If the coefficients of all the different powers of the unknown quantity from m downward are whole numbers, all the commensurable roots are whole numbers. Every equation in which some of the coefficients are fractional can be transformed into another of the same form as given above, in which all the coefficients shall be whole numbers; but in this case x will have to give place to some other unknown, as y in the expression $y=kx$. After the transformation we shall have $y^m+A'y^{m-1}+B'y^{m-2}+C'y^{m-3}\ldots\ldots P'x+Q'=0$.

Every equation can be transformed into another in which the second term shall be wanting by assuming $x=y-\frac{A}{m}$, and substituting this value of x for x itself in the given equation. This transformation is always necessary preliminarily to the reduction of cubics, and generally to that of biquadratics. Every equation in which the signs are all positive must have all its real roots negative. Every *complete* equation (*i. e.* one in which all the powers of x are present) which has its signs alternately positive and negative must have all its real roots positive; and this will be true of incomplete equations if we replace the missing terms by *zeros*. When the last (the known) term of an equation is positive, the number of its real positive roots is even; when it is negative, the number of such roots is uneven. Every equation of an even degree, in which the coefficients are real and the last term negative, has at least two real roots—one positive, and the other negative. Every equation of an odd degree, in which the coefficients are real, has at least one root of a sign contrary to that of the last term. When the roots of an equation are all real, the number of positive roots is equal to the number of variations of sign (changes from + to —, or the contrary in proceeding from left to right), and the number of negative roots is equal to the number of permanences of sign.

The number of real roots of any numerical equation in which the roots are all unequal may be found by means of its first derivative (see DERIVATIVE), as follows: Operate on the equation and its derivative as for finding greatest common measure, using only positive multipliers or divisors in preparing the several steps, and change the signs of the successive remainders thus found. Set down then in a row the first terms (only) of the given equation, the derivative, and the several remainders prepared as above (including the last remainder, which will have but one term), with their signs. Suppose the unknown to be positive, and write under each term of this row the sign of that term resulting from this supposition. Then suppose the unknown to be negative, and write under the sign last written the sign resulting from this second supposition. Count the number of variations in the first of these rows of resultant signs, and also the number of variations in the second of the rows. The difference between these numbers is the number of real roots in the original equation.

If, as above supposed, the original equation has no equal roots, no common measure will be found by the first operation above, and the last remainder will be a constant. But if it *has* equal roots, a common measure will be found. In this case divide the original equation by this common measure, and the quotient will be a new equation having the same roots as the given one, the equal roots of that equation entering it but once. Proceed with it as above. If the given equation contain but one set of equal roots, the greatest common measure found in the operation above described will be a binomial, or a complete power of a binomial; and the common value of the equal roots will be found by extracting the numerical root of the known term which corresponds in degree to this power. If the given equation contained more than one set of equal roots, the greatest common measure found as above will be the product of the same number of binomials or binomial powers; and by putting this equal to zero, and pursuing with it the same treatment as with the original equation, the number of real roots in it will be ultimately found.

If, instead of taking the *first terms* of the quantities above specified—viz. the equation, the derivative, and the remainders (with signs reversed)—those expressions be written out in full, and their resultant signs ascertained and written down for any assumed value of the unknown, as p, and for other values as p_1, p_2. . . . p_m, etc., increasing or diminishing by minute differences; and if at length a value, as p_m, be found which gives one variation more or one fewer than the value p_{m-1}, next greater, or next less; then one of the real roots of the equation lies between p_{m-1} and p_m. It thus appears that all the real roots of any numerical equation of whatever degree may be found by approximation.

F. A. P. BARNARD.

Equa'tion of Time is the difference in mean solar time between the sun's apparent or true right ascension and its mean right ascension; or, in other words, the difference between sun time and clock time. This difference arises—(1st) from the sun's unequal motion in longitude because of the eccentricity of the earth's orbit; (2d) from the obliquity of the ecliptic; and (3d) to some small extent from the perturbations of the moon and planets. Sun time and clock time agree about Dec. 25th, April 16th, June 16th, and Sept. 1st. The equation of time is greatest about Nov. 1st, when the clock is sixteen minutes and sixteen seconds faster than the sun.

Equa'tion, Per'sonal. It is found by experience that different persons, in recording the results of astronomical observations, will make various errors, some anticipating the event, but others failing to record it at the proper time. When it is found possible, by examining a long series of records made of the same events by two observers,

to discover the average difference between their records of events, a very important correction of time-intervals may sometimes be introduced into a computation based upon such records. Such a correction is called the relative personal equation of the two astronomers. When it is found that an observer habitually makes, or is likely to make, a certain error in his time-records, such error (or absolute personal equation) can be readily allowed for.

Equa'tor [Lat. *æqua'tor*, from *æquo*, *æqua'tum*, to "make equal:" Sp. *ecuador*], literally, "that which makes equal," or which divides equally the surface of the earth, in geography, is a great circle of the terrestrial sphere which is equidistant from the two poles, and divides the earth into northern and southern hemispheres. Latitudes are counted from the equator along the meridian, and longitudes are measured on the equator or on some circle parallel with it.

Equator, in astronomy, is the great circle of the celestial sphere, of which the plane is perpendicular to the axis of the earth's diurnal motion. It is called the equator because when the sun is in its plane the days and nights are exactly equal all over the world. The equator divides the sphere into northern and southern hemisphores, and is often styled the *equinoctial*. The apparent diurnal motions of all the celestial bodies are performed in circles which are parallel to it. The right ascensions are measured on it.

Equatorial Current. See Currents, Marine.

Equato'rial Tel'escope, a telescope mounted upon a fixed axis parallel to the axis of the earth, and turning also upon a second movable axis parallel to the equator, for the continuous observation of heavenly bodies, and for noting their right ascension and declination. The motion of the telescope round its fixed or "polar" axis is necessarily parallel to the equator, and this gives the instrument its name. In order to maintain the object observed steadily in the field of view, the telescope is made to revolve round the polar axis by an attached clockwork, which admits of being regulated so as to vary the velocity of rotation, according as the object under examination is the sun, the moon, a planet, or a fixed star.

Eques'trian [Lat. *eques'tris*, "belonging to a horse or horseman" (from *e'quus*, a "horse")], pertaining to horses; riding on horseback; skilled in horsemanship; representing a person on horseback, as a statue.

Eques'trian Or'der [Lat. *ordo eques'tris* or *equites*, the plu. of *e'ques*, a "horseman"], also called **Knights,** the name of an important division of the citizens of ancient Rome. They were originally a military organization, and formed the cavalry of the Roman army. According to Livy, Romulus constituted three centuries (300) of equites, to whom he gave the several names of Ramnenses, Titienses, and Luceres. Down to the year 123 B. C. the equites formed simply a division of the army, and their centuries were composed of patricians and plebeians, but C. Gracchus in that year procured the passage of the *Lex Sempronia*, which instituted a new class or political order called *ordo equestris*, from whom all the *judices* (judges) must be selected. The reform of Sulla deprived them of the sole right of being chosen as judices, who thenceforth were selected from the senators, equites, and *tribuni ærarii*. The equites also enjoyed the privilege of officiating as *publicani* or farmers of the public revenue. According to Cicero, who belonged to this order, these publicani "comprised the flower of the Roman chivalry, the ornament of Rome, the firm support (*firmamentum*) of the republic." The badges of the equites were a gold ring and a robe with a narrow purple border.

Eques'trian Stat'ue, a complete figure of a person on horseback, executed generally in bronze or stone. In ancient Greece, where plastic art attained its highest perfection, statues of men and of horses were often of the first excellence; but horses were more commonly represented as attached to the chariot. In Rome, equestrian statues of the emperors were common. The finest extant Roman work of the kind is a bronze equestrian statue of M. Aurelius Antoninus. Among the famous modern equestrian works are the noble colossal statue of Peter the Great at St. Petersburg, and that of Frederick the Great at Berlin by Rauch. Recent works of the kind are very numerous.

Equian'gular, having equal angles. A figure is equiangular when all its angles are equal, as a square. Two or more figures of the same kind (usually rectilinear) are said to be equiangular when the angles of the one taken consecutively are respectively equal to the angles of the other.

Equian'gular Spi'ral, a term applied to the logarithmic spiral, from its having the property of cutting all its polar radii vectores at the same angle.

Eq'uidæ [from the Lat. *equus*, a "horse"], the family which is formed by the horse, ass, etc., a section (Solidungula) of the order Ungulata. The most characteristic feature of the Equidæ is the solid, one-toed foot formed by the union of the central phalanges and the atrophy of the lateral ones. Single-toed horses began in the pliocene. In the miocene epoch our horses were represented by *Hipparion*, etc., which had two small lateral toes or hoofs, of which some traces may be often found in living horses. In the lower miocene *Anchitherium* represents the Equidæ, and connects the horse with *Palæotherium*, *Phiolophus*, etc. of the eocene and with the tapirs of the present day. The genealogy of the Equidæ is better known and more instructive than that of any other group of mammals. Nearly twenty species of equine quadrupeds have been described from the tertiary and quaternary deposits of America, but it is supposed that no horse existed with the New World at the time of the advent of the Europeans. (See Horse and Hipparion.)

Equilat'eral [from the Lat *æ'quus*, "equal," and *la'tus* (gen. *lat'eris*), a "side"], having equal sides. In geometry a rectilinear figure is said to be equilateral when all its sides are equal. If, moreover, its angles are all equal, it is called *regular*. Every equilateral figure inscribed in a circle is equiangular, and therefore regular. The converse theorem, however, is only true for polygons with an odd number of sides. An equilateral hyperbola is that of which the axes are equal.

Equilib'rium [Lat. *æquilibrium*, from *æ'quus*, "equal," and *li'bra*, a "balance;" Fr. *équilibre*], the state of rest produced by two or more mutually counteracting forces; equipoise. Equilibrium is the foundation of the theory of mechanics; it is, in its generalized meaning, *the physical law of the universe*. Equilibrium, in the fine arts, the just place or balance of a figure or other object, so that it may appear to stand firmly. Also the due equipoise of objects, lights, shadows, etc. against each other.

Equinoctial. See Equinox.

Equinoc'tial Points, the two opposite points of the celestial sphere in which the ecliptic and equator intersect each other, the one being the first point of Aries, and the other the first point of Libra. These points do not retain a fixed position in relation to the stars, but retrograde from E. to W. with a slow motion, requiring 25,000 years to accomplish a complete revolution. This motion is called the "precession of the equinoxes."

E'quinox [from the Lat. *æ'quus*, "equal," and *nox*, "night," *i. e.* the time when the night equals the day in length], in astronomy, the time when the sun passes through the equator in one of the equinoctial points. When the sun is in the equator the days and nights are equal all over the world, hence the derivation of the term. This happens twice every year—viz., about the 21st of March and the 22d of September; the former is called the *vernal*, and the latter the *autumnal* equinox. The equinoxes do not divide the year into portions of equal length, but the interval from the vernal to the autumnal equinox is greater than that from the autumnal to the vernal; in other words, the sun continues longer on the northern than on the southern side of the equator, because it is more distant from the earth in our summer than in winter, and its angular motion in its orbit is consequently slower between March and September than in the other part of the year. In 1800 the difference amounted to seven days sixteen hours and fifty-one minutes.

Eq'uipage [from the Fr. *équiper*, to "equip," to "fit out," to "furnish"] in ordinary language signifies the carriage, horses, and liveries which indicate the fortune or rank of a nobleman or gentleman; a carriage of state; a retinue; ornamental furniture. In marine affairs it signifies the crew of a ship, together with all a ship's furniture, masts, sails, ammunition, etc. In military language the term "camp and garrison equipage" is applied to the tents and other furniture of an army.

Equip'ment, the act of equipping or fitting for an expedition; furniture, accoutrements, or warlike apparatus. The equipment of a private soldier comprises his clothes, arms, and other necessary articles. In civil engineering the term is applied to the rolling stock of a railroad—*i. e.* the locomotives and cars.

Equipment and Recruiting, Bureau of, in the U. S. navy department, has charge of supplying cables, rigging, anchors, sails, blocks, and fuel for ships in commission. It controls the government ropewalks and other manufactories of that class of goods which it supplies. It also has control of naval enlistments of seamen, landsmen, and boys, and of the recruiting rendezvous and the receiving ships.

Equiseta'ceæ [from *Equise'tum*, one of the genera], a natural order of cryptogamous plants, growing in ditches, wet ground, and rivers in many parts of the world. They have no decided affinity with any known order, and have no medicinal qualities. They have hollow and jointed

stems. They are found fossil in coal, and were in ancient geologic periods very much larger and more numerous than at present.

Equise'tum [from *e'quus*, a "horse," and *se'ta*, a "bristle"], a genus of plants of the order Equisetaceæ, comprises numerous species called horsetail. The fructification is in the form of a cone or spike. To the base of each spore are attached four thread-like and club-shaped elastic filaments, which roll up closely around the spore when moist, and uncoil when dry. The *Equisetum hyemale* (scouring rush) is indigenous in the U. S. and also in Europe. The abundant silex in its cuticle renders it useful for polishing furniture and for scouring utensils. The U. S. have also several other species. True *Equiseta* date back to the trias, when they were numerous, and attained the height of twenty feet. In the carboniferous rocks the *Equiseta* are represented by *Calamites*, *Calamodendron*, etc.

Eq'uitant [from *eq'uito*, to "ride"], a botanical term signifying "riding astride," is applied to leaves which overlap each other without any involution, as those of the iris.

Equites. See Equestrian Order.

Eq'uity [Lat. *æquitas*, "equality," "justice," from *æquus*, "just," "even," "equal"]. This word is used to indicate a portion of the mass of English jurisprudence, derived from the decisions of courts and the rules of approved text-writers. It originated in the same general way as that branch of jurisprudence technically called "common law." It is, in a sense, common law itself when considered in contrast with statutes. The relation of equity to common law can be best understood by a brief historical survey. After the Norman conquest of England the king was deemed to be the fountain of justice. Ultimately, certain great courts of general jurisdiction came into active operation, known as "king's courts." These were the common pleas, the king's bench, and the exchequer. At first, their functions were quite distinct, but in course of time, by fictions of law, jurisdiction was assumed, so that in some respects it became concurrent in these tribunals. The regular mode of bringing a question before one of these courts for adjudication was by an action, in which there was a plaintiff and a defendant. A formal statement of the plaintiff's claim and of the defendant's defence was made in written allegations termed pleadings, and the question thus raised was called the issue. A judge and jury disposed of issues of fact. The action must be commenced by a so-called *writ*, purporting to emanate from the king and addressed to the sheriff, who caused the defendant to be brought before the court. There was an office in chancery, from which the writs issued. They were framed in a technical manner. The clerks would only grant a writ when they could find a precise precedent in their office. Actions were real, personal, or mixed. A real action was adapted to the recovery of land; personal actions were used to recover money; and the two were combined in a mixed action. The personal actions were framed on the theory either of contract or wrong (technically called tort). Originally, they were debt, covenant, and detinue in cases of contract; and in case of tort, trespass, trover, and replevin. The object of the action of debt was to recover a specific sum of money due to the plaintiff. The action of covenant was brought upon an instrument under seal. "Detinue" was resorted to in order to recover a specific chattel which the defendant had received as a bailee. (See Bailment.) The action of trespass was instituted for an immediate and direct injury to person or property; trover was the appropriate means to recover the value of personal property wrongfully converted by the defendant; while replevin was used to recover the property itself.

It was found at an early day that the personal actions were quite insufficient to give full relief. A statute was enacted in 13 Edw. I. (ch. 24) which led to the introduction of a new form of action, termed "trespass on the case." This was a comprehensive name for all actions for wrongs where the injury was indirect and consequential, as in the case of negligence. It also included many cases now recognized as strictly actions upon contract, and called "assumpsit." If this statute had been wisely interpreted, no court of equity would have been necessary, nor would any probably have arisen. But the judges of the so-called common-law courts adopted very strict and narrow rules of construction, and confined the remedy under the statute to the same kind of relief as had been already recognized. All the relief granted in these courts may be summed up in a single phrase: one can recover money only or specific real or personal property. As society advanced in wealth and civilization, such a system of remedial justice was lamentably imperfect. Out of its imperfection grew the jurisdiction of courts of equity. The residuum of justice not granted to the common-law courts remained in the king. It became a practice to address petitions to him in particular cases for relief which those courts could not grant. These were referred to the privy council, a powerful body of men selected by the monarch for their wealth or capacity. In process of time the disposal of these petitions devolved upon one of their number, the lord chancellor, who was a great officer, and who had usually the legal training which would fit him to dispose of the important questions submitted to him. Such matters were not presented by writ, as in the common-law courts, but by an application in the nature of a petition; and this commonly closed with the stereotyped phrase that the petitioner, having no sufficient remedy at common law, asked for relief "for the love of God and in the way of charity." At an early day the chancellor devised a writ called a writ of subpœna, whereby a party to a suit could be compelled to disclose upon his oath facts bearing upon the controversy between him and the opposite party. This is called "discovery." No such power inhered in common-law courts. In this way the court of chancery became a regular tribunal for the administration of justice. It followed precedent, and has worked out a scientific system of equity jurisprudence. It has now become so bound down by rules that new principles can only be introduced by legislation. This point is treated in a masterly manner by Mr. Maine in his work on "Ancient Law." It should be remarked that other courts besides the court of chancery acquired equity jurisdiction. Thus, the court of exchequer had until modern times equity powers. There may thus be courts of *equity* which are not strictly courts of *chancery*.

When English jurisprudence had assumed a precise and fixed character, there were thus two sets of tribunals, called respectively courts of common law and courts of equity. In some cases the jurisdiction of the two courts was concurrent; in others the equity court had exclusive authority, as in the case of trusts. The courts differed in three principal respects: two of these were in matters of procedure, while the third distinction was radical and substantial. They differed as to the mode of proof and of trial, and in respect to the nature of the relief granted. The first two distinctions have been largely modified in this country in a considerable number of the States. In these law and equity are administered by a single court and under the same system of pleading, so that there is no distinction between an action at law and a suit in equity. Even in these States the difference in relief still continues. When the action is for the recovery of money only, or of specific real or personal property, a writ issues to the sheriff to carry the judgment into effect. In other (or equity) actions, as when a defendant is required to execute or cancel a written instrument, or to refrain from doing an act, the order of the court is directed to him; and if he wilfully disobeys it, he may be punished for contempt of court. This consolidation of law and equity was first attempted in a "code of procedure" adopted in New York in 1848. This has been substantially enacted in a number of other States, and has had much effect upon legal opinion in England. Courts of equity have adopted certain maxims which have had a large influence on the development of the system. They are such as these: (1) Equity follows the law; (2) He who comes into equity must come with clean hands; (3) He who asks equity must do equity; (4) Where the equities are equal, the legal title must prevail; (5) Equality is equity; (6) Equity regards that as done which ought to be done.

A brief exposition of a few of these maxims will show the principles which guide the action of the court. The maxim that "He who comes into equity must come with clean hands," does not refer to general moral delinquency. It only applies to the subject before the court. It then assumes a comprehensive meaning. Under it the court would not protect the copyright of an immoral book, or a trademark which was so used as to deceive the public. The maxim that "He who asks equity must do equity," means that the court will only grant relief to a plaintiff upon the condition that he will render justice to the defendant. For example, a borrower could not succeed in setting aside an instrument on the ground of usury, except upon the condition of paying to the creditor the debt and lawful interest. The maxim that "Where the equities are equal, the legal title must prevail," means that the court will not, on the application of a plaintiff, deprive a defendant, being a purchaser for a valuable consideration, of a title recognized in a court of common law, unless he has acted in bad faith or with notice of the existing rights of the plaintiff. An illustration will show its application. If A has taken an informal mortgage upon land, and accordingly one not valid in law, and yet a good claim in equity, and B, without notice of A's rights, has taken, for a valuable consideration, a subsequent regular or formal mortgage or conveyance, B will have superior legal rights, which will be recognized in a court of equity. If B had acted with notice of the informal mortgage, A's equity would have been superior. The rule that "Equality is equity" is applied

to persons who ought to bear a common burden equally, as in case of the duty of co-sureties to contribute equally to pay the debt for which they are bound, or in cases of general average in the law of shipping. It is the principle which underlies the distribution of assets among creditors in cases of bankruptcy, or in the administration of the estates of intestates. The rule that "Equity regards that as done which ought to be done," is one of great importance. It leads to a doctrine peculiar to this court, known as "equitable conversion." This phrase means that the owner of property, by the mere expression of his will according to legal rules, can change its legal character, and thus give to money the qualities of land, or to land those of money. Thus, if a testator orders his land to be sold and converted into money, the land from the moment of his death is deemed to be personal property. The same result would follow if he had directed money to be laid out in land. So, if an owner of land contracts to sell it, his interest before any conveyance is made is deemed to be money, while that of the purchaser is regarded as land. This doctrine is attended with important practical consequences, to which the limits of this article do not permit a reference.

It is an important rule that the jurisdiction of this court attaches to the person of a litigant, without reference to the situation of the property in controversy. Thus, the court of chancery in England might order a defendant within its jurisdiction to execute a conveyance of land situated in this country. It would proceed upon the theory that he was under a legal duty or obligation to do the act which as a matter of conscience he was bound to perform. The court was at one time termed a "court of conscience," and in the older law digests or abridgments, the equity law is placed under that head. It should be added that mere gratuitous executory promises are not enforceable in this court. Attention is only paid to the claims of purchasers for a valuable consideration.

The topics of equity jurisprudence are usually considered by text-writers in their relations to the jurisdiction of the courts of common law. In this aspect equity jurisdiction may be regarded either as auxiliary to the jurisdiction of those courts, or as concurrent or exclusive. This method is necessarily discarded in those States where law and equity are administered under a uniform system of pleading and practice, as in New York. The principal subjects may be enumerated under the following heads: Cases of accident or mistake (as where a clause is omitted from an instrument by accident); cases of fraud, either actual or constructive; specific performance of contracts (*e. g.* requiring a party who has promised to execute a conveyance to fulfil his contract); cases of interpleader, whereby a mere stakeholder can be relieved from the results of a litigation; cases of accounts, including a variety of instances; cases of trusts, whether created by express words or arising from implication of law. The court also protects all persons under actual or legal disability, such as infants, married women, and persons of unsound mind. Under these and other heads the court may cancel, modify, or reinstate instruments, and in general adjust the rights of the respective parties to the controversy. In some of these cases actions may be brought in a court of law. Thus, in case of fraud, if the injured party desired pecuniary damages, he would bring his action at law; if he desired to set an instrument aside, he would proceed in equity. A person who would have a good defence on the ground of fraud to an action at law, may in some instances become plaintiff in equity, and have the instrument cancelled, as in the case of a negotiable promissory note. The most extensive of all of these topics is the subject of trusts. Strict trusts are solely cognizable in this court.

The remedies in this court are flexible and readily adapted to the exigencies of the case. The most liberal rules prevail as to parties. Every person can be made a party whose presence is necessary to a complete determination of the matter in controversy. The court has power to prevent apprehended injuries to property by means of an injunction, or to place the property itself in the possession of one of its own officers, termed a receiver, until the rights of the parties are finally established.

The tendency of modern times would seem to be to blend the two systems of common law and equity jurisprudence into one, when the common law will prevail as *modified* by the rules of equity. T. W. Dwight.

Eq'uity of Redemp'tion, the right which the owner of mortgaged property has to redeem it after the condition of the mortgage has been broken. A mortgage is in form a conveyance of property, with a provision that it shall be void on the performance by the maker, within a given time, of a certain condition, usually the payment of a sum of money; and by the common law, if the condition is not performed the conveyance becomes absolute, and the maker of the mortgage, called the mortgagor, loses all right to the property. But the English court of chancery, an equity tribunal, as early as the reign of Charles I. asserted its power to remedy this hardship by compelling the mortgagee to give up the land on payment of the debt with interest. This right in equity to redeem the property after the conveyance has become absolute at law has in modern times come to be regarded as an estate in the land, and can be conveyed or mortgaged or devised by its owner. It passes by descent to his heirs; it is liable for the debts of his creditors, and can be sold on execution against him, and is subject to dower and curtesy. This right to redeem lasts till cut off by foreclosure of the mortgage, which is usually effected by an action in a court of equity. The foreclosure may result in giving a complete title to the mortgagee (called a *strict* foreclosure), or it may result in a sale of the premises and the payment of the debt out of the proceeds, the surplus being returned to the mortgagor or to those who claim under him. The right to redeem from the mortgage extends to all who acquire an interest in the land under the mortgagor after the making of the mortgage; and all such persons must be made parties to a proceeding to foreclose the mortgage, otherwise their right to redeem will not be affected. Formerly, unless restrained by some clause in the mortgage, the mortgagee could at once take possession of the premises, although equity compelled him to account for the rents and profits upon redemption. Now, however, the mortgagor has in general the right of possession till the condition is broken, and in some States till foreclosure, except when after default, where the security is inadequate, a receiver is appointed to take charge of the property under the direction of the court. T. W. Dwight.

Equivalents, Chemical. See Chemistry.

Equiv'ocal Term, in logic, a term which has several significations applying respectively and equally to several objects. A word is generally said to be employed equivocally where the middle term is used in different senses in the two premisses, or where a proposition is liable to be understood in various senses.

Equus, the name of the genus which includes the horse, ass, zebra, etc., and type of the family Equidæ (which see).

E'ra [Lat. *æ'ra;* Fr. *ère,* probably from a root akin to the Basque *era,* "time"], a period of time; an account of time reckoned from some particular date or epoch; a succession of years computed from some fixed point of time.

Era, Christian. See Christian Era.

Érard (Sébastien), an inventor and maker of musical instruments, born in Strasbourg April 5, 1752. He was the son of a poor cabinet-maker. His first pianoforte, constructed in 1780, may be said to have introduced that instrument into France. He soon became the best pianoforte manufacturer in Europe. He, in connection with his brother, established a manufactory in London. To Érard the piano owes some of its noblest qualities as a musical instrument. The grand piano, with single and double action, was his invention. He built the great organ for the royal chapel of the Tuileries. The pianos of Érard still preserve their reputation, though great improvements have been made in the instrument since his day, in a very large degree by American manufacturers. Sébastien Érard was inventor of a double-action harp which had immense popularity in London, and took out patents for many other improvements, all of which were of value. Died near Paris in 1831. A nephew, who succeeded him in the business, wrote an account of his uncle's work.

Erased [from the Lat. *e,* "out" or "off," and *ra'do, ra'sum,* to "scratch," to "scrape"], in heraldry, signifies that an object is forcibly torn off, so that the edges are ragged or jagged.

Erasis'tratus [Gr. Ἐρασίστρατος], an eminent Greek physician and anatomist, is supposed to have been born in the island of Ceos. He flourished about 300–260 B. C., and practised for many years at Alexandria, where he taught anatomy and founded a school. He attended Antiochus, the son of Seleucus Nicator, at the court of the latter, and discovered that his malady was caused by a secret amorous passion for Stratonice, his stepmother. His principal discoveries were those of the *vinæ lactææ* and the functions of the brain and nerves. He wrote several works, which are not extant.

Eras'mus (Desiderius), [Fr. *Didier* or *Désiré Érasme*], a celebrated Dutch scholar and philosopher, born at Rotterdam on the 28th of October, 1465. He was a natural son of Gerard Praet, and was called in his childhood Gerhardus Gerhardi, which he exchanged for the Latin and Greek equivalents, each signifying "the well-beloved." He attended for about six years the school of the Brethren of the Common Life at Deventer, where he was a pupil of Alex-

ander Hegius. Having become an orphan about 1478, he was urged by his guardians to enter a monastery, in order that they might defraud him of his patrimony. Although he regarded a monastic life with aversion, he was at length induced in 1482 or 1483 to enter the Augustinian convent of Stein by the hope that he might there have opportunity for study. He pursued the study of the classics and distinguished himself as a Latin scholar. He became in 1492 a priest and secretary to the bishop of Cambray, with whom he remained nearly five years, and in 1496 went to Paris, privately, for the purpose of completing his education. He was there nearly destitute of pecuniary resources, and gained a subsistence in Paris by teaching school. Between 1498 and 1500 he passed about two years in England, where he formed friendships with Sir Thomas More and John Colet. He resided at both the universities, and during his third and longest visit (1511–14) was professor of Greek at Cambridge. Impelled by a strong passion for travel, he visited various countries of Europe, and never remained long in one place. In 1506 he commenced a tour in Italy, where he passed several years, perfected his knowledge of the Greek language, and associated with the most eminent scholars. He obtained from the pope a dispensation from his monastic vows, and received the degree of D. D. at Turin. He revisited England in 1511, and was appointed professor of Greek at Cambridge. In 1511 he published "The Praise of Folly" ("Stultitiæ Laus"), a witty satire, in which he exposed the follies and frailties of monks, priests, and men of various other professions. It was generally admired, and ran through a large circulation.

Having established his reputation as the most eminent scholar and the most witty writer of his time, he received invitations from several monarchs, and in 1514 or 1515 visited the court of the archduke Charles (afterwards Charles V.), who gave him the title of royal counsellor, with a pension of 400 florins, and liberty to travel or reside wherever he might prefer. He produced in 1516 a good edition of the Greek New Testament—the first edition ever printed—with a corrected Latin version and notes. He was on friendly terms with Luther in the first stage of the Reformation, which he efficiently promoted by his witty satires against the monks and priests, and by his censure of the corruptions of the Church of Rome. But he disliked dogmatism, was too liberal and moderate to please the zealous supporters of either side in a religious controversy, and he dissented from some of the doctrines of Luther, who denounced him in severe terms as a coward and time-server.

Erasmus became a resident of Bâle about the year 1515, and published there in 1527 his celebrated "Colloquies" ("Colloquia"), which some consider his capital work. It is ostensibly intended for the instruction of youth in Latin and morals, but abounds in satire and invective directed against the monks and the abuses of the Roman Church. It is stated that 24,000 copies of it were sold in one year. He was involved in a dispute with Luther on the doctrine of free will in 1524, and wrote on that subject "De Libero Arbitrio." He was condemned as a heretic by the Sorbonne of Paris, but he persisted in maintaining the attitude of a neutral or mediator, and never formally revolted against the pope. In 1529 he removed to Freyburg, where he passed several years. He died at Bâle on the 12th of July, 1536. Among his works is "Adagia," a collection of proverbs, which displays immense learning. He greatly excelled as an editor of the Greek and Latin classics, for which he was qualified by superior critical sagacity as well as accurate scholarship. He was pre-eminent as a restorer of classical learning and sound philosophy. His writings, as "Epistles" contain valuable materials for literary history. His complete works were published by Beatus Rhenanus (9 vols., 1540), and by Leclerc (10 vols., Leyden, 1703–06). (See Bonnaby, "Vie d'Erasme," 1757; Knight, "Life of Erasmus," 1726; Jortin, "Life of Erasmus," 1758; Adalbert Müller, "Life of Erasmus" (in German), 1828; Charles Butler, "Life of Erasmus," 1825; Gratama, "Erasmus als Kirchenreformator," 1868.)

Eras'tians, a name given to the adherents of the Swiss physician Erastus in church discipline. Erastus earnestly opposed the use by Protestant churches of excommunications and prohibitions, and held that the "church ought merely to declare who by soundness of faith were to be regarded as members, but should not take upon herself to punish moral offences by withholding her privileges. This view is particularly developed in his posthumous work, "Explicatio gravissimæ quæstionis utrum excommunicatio mandata Christi fuerit," etc. (1589). The common belief that Erastus intended to subject all ecclesiastical bodies in the control of the state authorities is at least an exaggeration. During the great conflict in the Church of Scotland which led to the establishment of the Free Church, those who maintained that the Church had no power to nullify by law the operation of lay patronage were called by their opponents Erastians, but they protested against this use of the word.

Eras'tus (Thomas), M. D., a Swiss physician and theologian, whose proper name was Lieber or Liebler, was born at Baden in Switzerland (according to others, at Angen, near Badenweiler), Sept. 7, 1524. He took the degree of M. D. at Bologna, wrote several medical treatises, and became a skilful practitioner. He was appointed physician to Frederick, the elector palatine, and was for many years professor of medicine at Heidelberg, which was the capital of that prince. As member of the church council he advocated the Zwinglian views of the Lord's Supper and of church discipline. He was charged with Sociniansism, but without just ground. In 1580 he obtained a chair of moral philosophy at Bâle, where he died Dec. 31, 1583. His views on church discipline excited much controversy. See Erastians.

E'rath, a county in N. Central Texas. Area, 1000 square miles. It is drained by Bosque River, which rises in it, and by Palucy Creek. The surface is broken and hilly, but is partly prairie. The soil is good. Stock-raising is the chief industry. Grain and wool are raised. Timber abounds, as well as building-stone. Capital, Stephensville. Pop. 1881.

Er'ato [Gr. Ἐρατώ], the sixth in order of the Nine Muses. She was the muse of the poetry of love, that being the significance of her name.

Eratos'thenes [Gr. Ἐρατοσθένης], a celebrated Greek astronomer and geometer, born at Cyrene in 276 B. C., was a pupil of Callimachus the poet. He became superintendent of the great library of Alexandria in the reign of Ptolemy Euergetes, and rendered important services to the sciences of astronomy and geography. He displayed great versatility of genius, and wrote numerous works on philosophy, history, grammar, etc. Among his memorable performances was the measurement of the obliquity of the ecliptic, which he computed to be 23° 51′ 20″. In an attempt to ascertain the dimensions of the earth he invented a method which has been employed with success in modern times. His writings are not extant, but fragments of his work on chronology have been preserved by Syncellus. His computation of Egyptian chronology has been adopted by Bunsen. "Eratosthenes was," says Bunsen, "next to Aristotle, the most illustrious of Greek men of learning, and as far superior to him in the extent of his knowledge as inferior in grasp of intellect." Died about 196 B. C. The fragments of his works were published by Bernhardy (1822).

Er'ben (Henry), U. S. N., born Sept. 6, 1802, in the city of New York, entered the navy as a midshipman June 17, 1818, became a passed midshipman in 1825, a lieutenant in 1830, a lieutenant-commander in 1842, a commander in 1855, took part in the engagements at Fort Pillow, Memphis, Vicksburg, and Baton Rouge during the year 1862, and in 1863 in the operations against Fort McAllister, Ga., and Forts Sumter and Moultrie, S. C.

Fitzhall A. Parker, U. S. N.

Er'bium (named from the last two syllables of Ytterby, a town of Sweden, whence gadolinite is procured), a rare dyad earth-metal, chiefly procured as an oxide called erbia, from gadolinite, along with yttria, with cerite existing naturally as silicates. Metallic erbium (atomic Eb atomic weight, 112.6) has not been separated. Its salts have mostly a rose-color.

Erci'lla y Zuñi'ga (Alonso), a Spanish epic poet, born Aug. 7, 1533, was a son of Fortunio Garcia, lord of Ercilla. He was in his youth a page of Philip II., whom he accompanied in a voyage to England in 1554. Having enlisted in the army, he went to South America in that year to fight against the Araucanians, a warlike tribe which the Spaniards were never able to subjugate. He served with distinction in this war, returned to Spain in 1562, and published his "Araucana" (first part, 1569), which is considered the best heroic poem in the Spanish language, and is said to be a faithful narrative of the events which he had witnessed. He was afterwards a gentleman of the bedchamber to the emperor Rudolph II., but appears to have passed his latter years in poverty and obscurity. Died after 1595. (See Ticknor, "History of Spanish Literature.")

Erckmann-Chatrian, the name of two French novelists whose works are usually published with whose names (pseudonyms) Erckmann and Chatrian are inseparably united. Émile Erckmann, born at Pfalzburg May 20, 1822, was the son of a bookseller, and after studying at the college of Pfalzburg applied himself to reading law in Paris. Alexandre Chatrian was born at Soldatenthal, near Pfalzburg, Dec. 18, 1826, and was an usher in the Pfalzburg college when he made the acquaintance of Erckmann in 1847. The two became fast friends and composed numerous stories, feuilletons, and dramatic pieces without much

success. Unable to live in this way, Erckmann applied himself to the law, while Chatrian found employment in a railway-office. "L'Illustre Docteur Mathéus" (1859) was the first of their writings which attained any popularity. Their novels upon the events of the Revolution and the First Empire were much read, and after the German annexation of Alsace they produced a novel under the title of "The Story of the Plébiscite, related by one of the 7,500,000 who voted Yes," which made quite a sensation. Also, their drama "Le Juif Polonais" was very successful.

Ercsi, an Hungarian town, in the county of Stuhlweissenburg, on the Danube, 18 miles S. S. W. from Pesth. Its industries are weaving, brewing, and tilemaking. Pop. 5540.

Erd'mann (Johann Eduard), born June 13, 1805, in Livonia, became professor of philosophy at Halle in 1836. He wrote, among other works, "Versuch einer wissenschaftlichen Darstellung der Geschichte der neueren Philosophie" (3 vols., 1834–53), "Grundriss der Logik und Metaphysik" (4th ed. 1864), and "Grundriss der Geschichte de Philosophie" (2 vols., 1866).

Erdmann (Otto Linné), a German chemist, born at Dresden April 11, 1804. He became in 1830 professor of chemistry at Leipsic. Died Oct. 9, 1869. Among his works is a valuable "Manual of Chemistry" (1828). He published after 1834 the "Journal für praktische Chemie."

Er'ebus [Gr. Ἔρεβος, probably from ἐρέφω, to "cover"], in classic mythology, the son of Chaos; also the name of a dark and gloomy region or subterranean cavern through which souls were supposed to pass after death.

Erebus, Mount, and Mount Terror, are two volcanoes in South Victoria Land, in lat. 77½° S., discovered by J. C. Ross Jan. 27, 1841. Mount Erebus, 12,400 feet high, is, as far as is known, the nearest volcano to the south pole, and when discovered was emitting flame and smoke in great profusion. Mount Terror, 10,900 feet high, is believed to be an extinct volcano. These two mountains were named from the British ships in which Ross's expedition sailed.

Erechthe'um [Gr. Ἐρεχθεῖον], in ancient Athens a sacred edifice on the Acropolis, consisting of the two temples of Athena Polias and Pandrosus. Its name was derived from Erechtheus (see below). It was burned by the Persians, rebuilt about 393 B. C., and became the most sacred of all the Athenian sanctuaries. The renewed Erechtheum was a most beautiful structure of the Ionic order. Unlike all other Grecian temples, it had three porticoes. It anciently contained a salt-well made by Poseidon's trident (not flowing in modern times), also the sacred olive tree of Athena, and the olive-wood image of that goddess, which is fabled to have fallen from the sky. The ruins of the Erechtheum stand north of the Parthenon, and are among the most interesting relics of antiquity. The six caryatides (gigantic female figures gracefully draped) which supported the roof of the southern portico are particularly fine. One of these is now in the British Museum.

Erech'theus [Gr. Ἐρεχθεύς; Fr. *Érecthée*], a hero of ancient Greek legends, was said to be a son of Vulcan or of Pandion, and the father of Cecrops. Homer represents him as a king of Athens. According to tradition, he was the founder of the Erectheum, a temple of Minerva on the Acropolis of Athens. He was sometimes called *Erichthonius*.

Er'egleé', or **Erekli** (anc. *Heraclea*), a seaport of Asia Minor on the Black Sea, 122 miles E. by N. of Constantinople. It has a good harbor, from which timber, silk, and wax are exported. The ancient *Heraclea* was an important town. Lat. 41° 17′ N., lon. 31° 25′ E.

Ere'tria [Gr. Ἐρέτρια; Fr. *Érétrie*], an ancient city on the island of Eubœa, is mentioned by Homer ("Iliad," book ii.). At an early period it was a prosperous and independent state, and one of the chief maritime cities of Greece. It was captured and ruined by the Persians in 490 B. C., but was soon rebuilt. Eretria was the seat of a celebrated school of philosophy, founded by Menedemus about 330 B. C.

Er'furt, or **Erfurth** [Lat. *Erphordia* and *Erfurtum*], a fortified town of Prussian Saxony, on the river Gera and the Thuringian Railway, 15 miles W. of Weimar and 14 miles E. of Gotha. It is defended by two citadels, and is important as a military position. It has an old Gothic cathedral with a bell which weighs 275 hundredweight, fourteen Protestant churches, a royal academy, a public library of about 50,000 volumes, a normal school, and an edifice formerly occupied by the University of Erfurt, which was founded in 1392 and closed in 1816. Here was the Augustine convent of which Luther was an inmate for several years; it is now used as an orphan asylum. Erfurt has manufactures of cotton and woollen fabrics, hosiery, shoes, leather, etc. It was more populous in the Middle Ages than it is now. The Congress of Erfurt, held here in Sept.–Oct., 1808, was attended by Napoleon and Alexander I. of Russia. In March and April, 1850, the so-called "Union Parliament" held its sessions here. (See Germany.) Pop. in 1871, 43,616.

Er'got [from the Fr. *ergot*, a "cock's spur;" Late Lat. *ergota*; Ger. *Mutterkorn*], or **Spurred Rye,** a curious fungus, the compact mycelium of the *Claviceps purpurea* of Tulasne, growing frequently in the heads of rye, though found on all grasses and some Cyperaceæ. It was long believed to consist of diseased kernels of rye, but microscopical examination shows that it has nothing at all in common with the rye, but growing originally from the ovary, it naturally assumes something of the shape of the mould in which it grows. It is believed that spores of this plant are taken up by the roots of the rye, and that they germinate in the ovary, where they are deposited from the sap.

Ergot is generally procured from rye after threshing. It is usually shaped somewhat like a cock's spur, and is from half an inch to one inch and a half long. It contains a volatile alkaloid secalia, identical or perhaps only isomeric with propylamia; also ergotic acid, and several other compounds which are little understood, including an oil which appears to be inert, and mycose, a peculiar sugar.

Ergot is much used in medicine, especially for the purpose of exciting uterine contractions in child-bearing. As a rule, it should never be administered except by persons skilled in its use. The contractions induced by ergot differ from the natural uterine effort, which is intermittent, with intervals of more or less perfect rest, while ergot causes a uniform and constant expulsive effort. In skilled hands it is a remedy of great value. Administered late in labor, it often prevents dangerous loss of blood, and it is further useful in some cases of menorrhagia and other hæmorrhages. It is also useful in puerile paralysis, and probably in other diseases requiring treatment which produces contraction of the muscular coat of the blood-vessels.

Er'gotism, or **Rapha'nia,** a disease or train of symptoms produced by the long-continued use of grain in which ergot is mixed. It is characterized by stupor, convulsions, diarrhœa, and vomiting, often accompanied by morbid increase of appetite, by purpura, and at last by a dry, chronic gangrene of the extremities. Rye and wheat are especially apt to be infested with ergot when sown late in the season; and in some years the ergot has been observed in parts of Europe to exceed one-fourth of the whole amount of the winnowed grain; and several severe epidemics of this fatal disease have been observed in Europe. It is rare in the U. S., but in 1819 the cattle throughout a part of the State of New York suffered extensively from an epizootic of this nature, caused by ergot in the blue-grass crop (*Poa pratensis*). The poisonous qualities of the darnel grass (*Lolium temulentum*), so well known even in Virgil's time, are now ascribed to the presence of ergot, which is well known to infest many of the grasses. The treatment to be pursued is a supporting one—the use of concentrated food, stimulants, pure air, bathing, friction of the skin, with gentle purgation. No antidote to the severer effects of ergot is known.

The medicinal use of ergot is very seldom followed by any of the above-mentioned symptoms, but a few well-established cases are on record, showing the danger of excessive and long-continued use of the drug.

Er'ic XIV., king of Sweden, born Dec. 13, 1533, was a son of Gustavus Vasa, whom he succeeded in 1560. He made an overture of marriage to Queen Elizabeth of England, but he married a Swedish peasant named Catharine Monsdoter. He was capricious, imprudent, momentarily insane, and always addicted to violent paroxysms of anger and cruelty. In his reign Sweden was involved in a war against Denmark. Several noblemen were unjustly put to death by his order. A conspiracy was formed against him by his own brothers and other nobles, who deposed him in 1568, and confined him in prison, where he died Feb. 16, 1577.

Erica'ceæ, or **Heathworts** [from *Erica*, one of the genera], a large natural order of beautiful exogenous plants, mostly shrubs, natives of Europe, Asia, South Africa, and North America. The leaves are entire, generally evergreen, and rigid or coriaceous. The anther is 2-celled. This order comprises about 900 known species, many of which have beautiful flowers. Among those which are natives of the U. S. are the Kalmia, Vaccinium, Azalea, Rhododendron, Pyrola, Gaultheria, Clethra, and Epigæa, which will be noticed under their respective heads. The genus *Erica* (heath) abounds in South Africa. (See Heath.) Many of the Ericaceæ are social plants, and a single species in some cases covers a tract of ground, of which it forms the almost exclusive vegetation. Several species bear edible berries, as *Vaccinium* and *Gaultheria* (wintergreen).

Er'icsson (John), LL.D., an eminent mechanician, was born in Vermeland, a province of Sweden, July 31, 1803.

Showing decided mechanical ingenuity in childhood, he was appointed at the age of eleven to a cadetship in the engineer corps, in which he rose to a lieutenancy. In 1826 he visited England to introduce a "flame engine" of his own invention, but it was discovered that though it worked with a wood-fire, it failed when coal was used. He made improvements in steam boilers, and in 1829 produced a locomotive, the "Novelty," which ran fifty miles an hour, a great advance in speed over anything then attained, winning a prize of £500. He soon after made a steam fire-engine (1832) and a hot-air engine (1833). He also first successfully applied the screw to the propulsion of steam-vessels; but the invention not being at first well received in England, he came in 1839 to New York, and the U. S. screw-steamer Princeton was built under his direction. Since then, this invention, with many modifications, has come into very extensive use. In 1852 the ship Ericsson, propelled by hot air, was launched. He has also invented a "solar engine," a pyrometer, an alarm barometer, a sea-lead, a hydrostatic gauge, and numerous other ingenious instruments. Mar. 9, 1862, his iron-clad vessel, the Monitor, just built, attacked and repulsed the Confederate iron-clad ram Virginia, formerly the U. S. steamer Merrimack. Thus Ericsson has the honor of first successfully employing the armed turret in naval shipbuilding.

Eric the Red, a reputed discoverer of America, was a Norwegian who emigrated to Iceland about 982 A. D. He made a voyage to Greenland, and there founded a colony. In 1000 A. D. his son Liefr sailed southward, visiting a country called by him Markland (perhaps Nova Scotia), and another called Vinland, which appears to have been South-eastern New England. With far less probability it is said that Eric planted a colony in Vinland.

E'rie, a county in the W. of New York. Area, 1071 square miles. It is bounded on the N. by Tonawanda Creek and on the W. by Lake Erie and Niagara River. It is drained by Buffalo Creek and other streams. The surface is undulating; the soil fertile. Dairy products, grain, wool, hay, fruit, and cattle are the staples. The manufactures and commerce are treated of in the article on BUFFALO (which see). Iron ore and limestone are found here. It is intersected by the Erie Canal, the Buffalo New York and Philadelphia, and the Lake Shore and Michigan Southern R. Rs., and by several branches of the Central and Erie R. Rs., converging to Buffalo, which is the capital of the county. Pop. 178,699.

Erie, a county in the N. of Ohio. Area, 250 square miles. It is bounded on the N. by Lake Erie, and intersected by Huron and Vermilion rivers. The surface is nearly level; the soil is alluvial and very fertile. Cattle, grain, wool, hay, fruit, and dairy produce are raised. The fisheries are important. The manufactures include flour, clothing, wine, brick, cooperage, shipping, carriages, etc. Fine limestone valuable for building abounds here. This county is traversed by the Lake Shore and Michigan Southern R. R., the Sandusky Mansfield and Newark R. R., and the Cincinnati Sandusky and Cleveland R. R. Capital, Sandusky. Pop. 28,188.

Erie, a county constituting the N. W. extremity of Pennsylvania. Area, 740 square miles. It is bounded on the N. W. by Lake Erie, and partly drained by Conneaut and French creeks. The surface is mostly undulating; the soil is clayey and productive. Cattle, grain, wool, potatoes, hay, dairy products, and fruit are the staples. Flour, leather, lumber, machinery, iron, saddlery, carriages, furniture, and metallic wares are manufactured. Sandstone and slate occur here as surface-rocks. It is intersected by the Philadelphia and Erie, the Erie and Pittsburg, the Atlantic and Great Western, the Buffalo Corry and Pittsburg, and the Lake Shore and Michigan Southern R. Rs. Capital, Erie. Pop. 65,973.

Erie, a post-village of Boulder co., Col., on the Boulder Valley R. R., 34 miles N. E. of Denver. It is an important coal-mining centre.

Erie, a post-township of Whiteside co., Ill. Pop. 695.

Erie, a township of Miami co., Ind. Pop. 599.

Erie, a township and post-village of Neosho co., Kan. Pop. 1350; of village, 418.

Erie, a post-township of Monroe co., Mich. Pop. 1527.

Erie, a post-township of McDonald co., Mo. Pop. 615.

Erie, a township of Ottawa co., O. Pop. 455.

Erie, a city and the county-town of Erie co., Pa., is the only lake-port of the State. It has the largest land-locked harbor on Lake Erie, being 5 miles in length by 1 in width. The Pennsylvania R. R. Company runs a line of first-class propellers between this port and the upper lakes, and over fifty sailing-vessels are owned here. The imports are principally grain, lumber, and iron ore, and the exports bituminous and anthracite coal and the merchant and pig iron, engines, and other manufactured products of the port. It is very nearly equidistant from Cleveland and Buffalo on the Lake Shore R. R., which gives communication E. and W., and is the northern terminus of the Philadelphia and Erie R. R., which penetrates the lumber-region of the State, and also gives connection with Harrisburg and Philadelphia and the anthracite coal-fields. Erie is also the northern terminus of the Erie and Pittsburg R. R., which passes through the bituminous coal-regions. The Pennsylvania Petroleum R. R., now building, will give direct communication with the oil-producing section, and furnish a competing route to the bituminous coal-mines. The facilities for the receipt of raw material and cheap fuel, and the shipment of products by rail and water, have given Erie manufacturing interests a great impetus since about 1866. A brief summary shows 24 iron-works, including a car manufactory producing 15 complete cars and 300 wheels per day; a blast-furnace, a rolling-mill, 2 very large stove-foundries, 4 tanneries, 2 boot-and-shoe factories, 6 oil-refineries, 1 church-organ and 2 parlor-organ factories, 1 piano-factory, 1 paper-mill, 13 planing-mills, 4 pump-factories, 2 spice-mills, 7 breweries, 3 malt-houses, 5 brick-yards, 1 stoneware-factory, 2 lime companies, 4 steam flouring-mills, 2 grain-elevators, 10 chair, carriage, and other woodworking factories, 1 daily and 6 weekly newspapers, etc. Erie is the market for a rich farming country. It has a custom-house, 4 national banks, 26 churches, 1 academy, a very complete free-school system, and water-works which cost $750,000. It is already the largest and most central point in a section covering the ten north-western counties of Pennsylvania, and its growth henceforth promises to be marvellous. Pop. 19,646.

F. A. CRANDALL, ED. "GAZETTE."

E'rie Canal', the most important, as well as the largest, canal in the U. S., extends from Buffalo to Albany, N. Y., and is 363 miles long. De Witt Clinton, whose name is identified with the construction of this great public work, was in 1809 appointed a member of a commission to explore and survey a route for the proposed canal from the lakes to the Hudson; and his memorial to the State legislature in 1815 ensured the success of the undertaking. The bill for its construction was passed in 1817, but the "canal policy" was for years strenuously opposed. In 1825 the canal was completed at a cost of $7,602,000, and navigation was opened in October with great rejoicings. Its original width was forty feet at the surface, with a depth of four feet; but the canal has been subsequently so enlarged that the surface-width is seventy feet, the bottom-width forty-two feet, and the depth seven feet. The commercial importance of this canal is very great. It is chiefly employed for transporting grain and such other bulky articles as do not require quick transit. (See INLAND NAVIGATION.)

Erie, Lake, one of the chain of great lakes drained by the St. Lawrence, is bounded on the N. by Ontario, a province of the Dominion of Canada, and on the S. by Ohio, Pennsylvania, and New York. It is the lowest of that chain of lakes, except Lake Ontario, into which its water is discharged through the Niagara River. It is 290 miles long, is 57 miles wide at the broadest part, and has an area of about 10,000 square miles. The surface is 334 feet higher than Lake Ontario. It is shallow compared with the other lakes of this series, the greatest depth yet obtained being 312 feet. The mean depth is about 120 feet. The principal supply of water comes through Detroit River, which enters the W. end of the lake. The chief cities on its shores are Buffalo, Cleveland, Toledo, Erie, and Sandusky, which have good harbors. This lake is very important as a channel of trade and steam navigation. It is liable to violent storms, which sometimes cause disastrous shipwrecks. Large vessels can pass from Lake Erie into Lake Ontario through the Welland Canal. The navigation of the former is suspended for three or four months in winter, in consequence of the shallow parts being frozen. The fisheries are important.

Com. Perry of the U. S. navy gained an important victory over the British commander Barclay in the western part of this lake, Sept. 10, 1813. This was called the battle of Lake Erie, and was fought near the Bass Islands, about 36 miles E. of Toledo.

Erie Shale, the name given by the Ohio geologists to the westward extension of the Chemung and Upper Portage rocks of New York. The oil-wells of Western Pennsylvania are bored on this foundation, though the petroleum which is found in it emanates from the Huron shale below.

E'rieville, a post-village of Nelson township, Madison co., N. Y., has 3 churches and an important canal reservoir.

Erig'ena (*i. e.* the "Irishman"), (JOHANNES SCOTUS), the boldest and most brilliant thinker of his century. The events of his life are involved in some obscurity. He was

probably born in Ireland between 800–815 A. D., and educated in the Irish monasteries. Between 840–845 he appears to have gone to France, where he was patronized by Charles the Bald. He is credited with one of the best repartees on record. At table one day the king asked him, "Quid distat inter Sotum et Scotum?" Erigena instantly replied, "Mensa tantum." What happened to him after the death of Charles the Bald, in 877, is not so clear. According to one account, he went to England about 883, on the invitation of Alfred the Great, and was murdered by his pupils at Malmesbury in 891. Some who deny the Malmesbury story, say that Scotus Erigena has been confounded with an Anglo-Saxon monk whom Alfred invited over from France to teach at Oxford. Erigena has been called "the morning star of scholasticism." He rebelled against Augustinianism, asserted the supremacy of reason, and wrought out a vague pantheism. He also translated into Latin the works (spurious) of Dionysius the Areopagite (of the fourth or fifth century), and thus planted the seeds of the mediæval mysticism. He wrote against Gottschalk (851 A. D.) on predestination, and against Paschasius Radbert on transubstantiation, and was condemned as a heretic at Paris in 1209. Of his other works, the most important is a treatise in five books, "De Divisione Naturæ." It was printed at Oxford in 1681. (See THEODOR CHRISTLIEB'S "Leben und Lehre des Johannes Scotus Erigena," 1860; and JOHANNES HUBER'S "Johannes Scotus Erigena," 1861.)

Erig'eron [Gr. ἠριγέρων, "early old," from ἦρ, "spring," and γέρων, an "old man," because the plants have a hoary appearance], a genus of herbs of the order Compositæ, including the fleabanes (which are weeds of several species, very common in Europe and North America) and other plants, such as poor robin's plantain (*Erigeron bellidifolium*), etc. The *Erigeron Philadelphicum*, *Erigeron Canadense*, and others are used as diuretics, and contain a volatile oil which varies somewhat in different species. The oil has a pungent, disagreeable odor, and sometimes takes on a tarry or oleo-resinous character. It is used in medicine.

Erin. See IRELAND.

Er'in, a post-village and township of Wellington co., Ontario, Canada, has quarries of building-stone and manufactures of various kinds. Pop. of village, about 600.

Erin, a township of Stephenson co., Ill. Pop. 877.

Erin, a township of Macomb co., Mich. Pop. 2466.

Erin, a township of Rice co., Minn. Pop. 526.

Erin, a post-township of Chemung co., N. Y., has a valuable mineral spring and manufactures of lumber. Pop. 1392.

Erin, a post-village, capital of Houston co., Tex.

Erin, a post-township of St. Croix co., Wis. Pop. 1024.

Erin, a township of Washington co., Wis. Pop. 1266.

Erina'ceus, the genus that includes the hedgehogs of the Old World, of which there are several species, inhabiting Asia, Africa, and Europe. The common hedgehog of England may be considered a type of the group. It is a harmless little nocturnal animal, which subsists mainly on insects, though sometimes eating fruit and even reptiles. The back of the hedgehog is covered with spines, and when attacked he rolls himself into a ball from which they radiate in every direction, and serve as a defence that enables him to defy all his enemies but man. Zoologically, the hedgehog is of special interest, as he stands at the head of the order of Insectivora, and, though the sport of the schoolboy and scorn of his dog, he is king of the moles and shrews.

Erinaceus Europæus, the European Hedgehog.

Erin'na [Gr. Ἤριννα], a Greek poetess who lived about 600 B. C., and was a friend of Sappho. She acquired a high reputation by her lyric and other poems, among which was "The Distaff." It is said that she died at the age of nineteen.

Erin'nys [Gr. Ἐρινύς or Ἐριννύς; plu. **Erin'nyes**], a name given to the Furies or EUMENIDES (which see).

Eriocaulona'ceæ [from *Eriocaulon*, one of the genera], a natural order of herbaceous endogenous plants, are nearly allied to Restiaceæ. They are mostly natives of the tropical parts of America and Australia. Many of the species are aquatic or grow in marshes. The flowers grow in close heads. Some of the *Eriocaulons* of Brazil are six feet high. Those of the U. S. are stemless. The *Eriocaulon septangulare* (pipewort) is indigenous both in the U. S. and in Ireland, and is interesting in reference to geographical distribution. It grows in ponds. Three genera and seven species of the order are found in the Atlantic States.

Erioden'dron [from the Gr. ἔριον, "wool," and δένδρον, a "tree"], a genus of trees of the natural order Sterculiaceæ, natives of tropical climates. They have large and beautiful flowers. They are sometimes called wool trees, because the capsules enclose a fibrous woolly or cottony substance. The cotton of *Eriodendron Samanna* is used in Brazil for stuffing pillows. The *Eriodendron anfractuosum*, which grows in the East Indies, Africa, etc., has edible seeds about the size of a pea. Other species yield useful medicines. The cotton produced by these trees cannot be spun, but its use in the paper manufacture has been proposed.

Erivân' [Lat. *Erivana;* Pers. *Revân* or *Revân*], a fortified town of Russian Armenia, in the government of Erivan, on the river Zenga, an affluent of the Aras, and near the latter river, 115 miles S. by W. from Tiflis. It has a citadel on a high rock, several Armenian churches, a large bazaar, and a few mosques; also a cannon-foundry and manufactures of cotton goods, earthenware, and leather. It was stormed and taken by the Russian general Paskewitch in 1827, and was ceded to Russia by Persia in 1828. Pop. in 1867, 14,342.

Er'langen, a handsome town of Bavaria, on the river Regnitz and on the railway from Bamberg to Nuremberg, 11 miles N. of the latter. It is enclosed by walls, and is divided into the old and new town, the latter of which is very well built. Here is the University of Erlangen, which was founded in 1742, and is celebrated as a school of Protestant theology. It has a library of 100,000 volumes, and a botanic garden. Erlangen has manufactures of hosiery, gloves, mirrors, plate glass, combs, and hats. Pop. in 1871, 12,511.

Erlau, ĕr'lou [Hung. *Eger*], a fortified episcopal city of Hungary, capital of the county of Heves, is on the river Erlau or Eger, about 75 miles E. N. E. of Pesth. It is enclosed by walls, and is pleasantly situated amid vine-clad hills. It has a cathedral, a bishop's palace, a gymnasium, a normal school, a lyceum, and a richly endowed hospital. Here are manufactures of linen and woollen fabrics. Erlau has an extensive trade in red wine of superior quality, which is produced in the vicinity. A bishopric was founded here in the eleventh century. Pop. in 1869, 18,150.

Erl'king [Ger. *Erlkönig;* Dan. *Elverkonge*, i. e. "king of the elves"], in German and Scandinavian mythology, a fabulous being, which through seductive allurements causes injury and destruction to human beings, especially to children. This tale has become widely known through the ballad of that name by Goethe.

Er'man (GEORG ADOLF), a German natural philosopher, born in Berlin May 12, 1806. He performed in 1828–30 a voyage around the world, during which he made a series of magnetic observations, and published a "Voyage Around the World, through Northern Asia and the Two Oceans" (5 vols., 1833–42). He became professor of physics in the University of Berlin.

Erman (PAUL), a natural philosopher, the father of the

preceding, was born in Berlin Feb. 29, 1764. He became professor of physics in the university of that city and secretary of the Academy of Sciences. He wrote on electricity and other branches of physics, as well as mathematical and other subjects. Died Oct. 11, 1851.

Ermenonville, a village of France, department of Oise, 7 miles S. E. of Senlis. Here is a beautiful château with an extensive park, which is visited in summer by many Parisians. Among the attractions of the place is the tomb of J. J. Rousseau, who died here in 1778.

Ermine, er'min, in heraldry, one of the furs used in blazonry. It represents the skin of the ermine, white, spotted or timbered with black. The arrangement of the spots varies with the wearer's rank. A black fur with white spots is called *contre ermine* or *ermines*.

Ermine, or **Stoat** (*Putorius erminea*), a carnivorous

Ermine or Stoat.

animal nearly allied to the weasel, which it resembles in its slender form and its habits, but it is larger and has a longer tail. It is a native of the northern parts of Asia and Europe, and perhaps of America. It is about ten inches long, exclusive of the tail. In the summer the color of the upper parts is a pale reddish brown, and that of the under parts nearly white. In winter the whole of the body is covered with white fur, slightly tinged with yellow, but the tip of the tail remains black in all seasons. The fur is closer and finer in winter, and that which is obtained from Siberia, Norway, and other cold countries is one of the most valuable of furs. It is used for ladies' winter apparel and for the robes of kings and nobles. When made up the tails are inserted one to each skin, at regular distances and in the quincunx order or otherwise, according to the wearer's rank. The fur called miniver is a variety of spotted, "powdered," or "timbered" ermine. The ermine fur forms the distinctive doubling of the state robes of sovereigns and nobles, as well as of their crowns and coronets. It is also worn by judges in some countries. The ermine preys on mice, poultry, eggs, young rabbits, etc. Most of the so-called ermine fur of commerce is simply white rabbit fur, with spots of black rabbit fur inserted.

The U. S. have several white weasels which are properly classed as ermines, having white winter fur and the tip of the tail black. Such are *Putorius noveboracensis*, or common white weasel; *Putorius Kanei*, or Kane's ermine, of Alaska and Siberia; *Putorius Cicognonii*, a small species; *Putorius Richardsonii*, called little ermine; *Putorius longicauda*, or long-tailed ermine, etc. North America, however, furnishes a very small part of the ermine fur of commerce.

The ermines, like the other weasels, have the power of emitting a most offensive odor when irritated. The common stoat of Great Britain produces a fur much inferior to that of the same species in the far North. It is regarded as vermin, and zealously hunted by foresters, warreners, and park-keepers, for it is a most destructive pest among rabbits, hares, and fowl, wild and domestic. It is caught in snares or traps. It is most active by night.

Erne, ern [from the Ang.-Sax. *earn*, an "eagle"], or **Sea Eagle** (*Haliaëtus*), a genus of eagles differing from other eagles in having no feathers on the toes and the lower part of the tarsi, also in the greater length of the bill. They have less courage than the eagle, and resemble the vulture in feeding on carrion as well as other prey. The common erne, cinereous eagle, or sea eagle (*Haliaëtus albicilla*) is the only species known in Great Britain. It makes its nest on the ledges of high precipices on the sea-coast, and sometimes near inland lakes, feeding on fish and waterfowl. It is about thirty-three inches long, the plumage brown, with a paler tinge on the head, and the tail of the adult pure white. The American white-headed eagle or bald eagle (*Haliaëtus leucocephalus*) is found throughout the whole of North America, frequenting the sea-coasts as well as the mouths of large rivers. (See Bald Eagle.) There is also an Australian species (*Haliaëtus leucogaster*) and the Pondicherry kite (*Haliaëtus Ponticerianus*), an Indian species, both of smaller size than the sea eagle.

Erne, a river of Ireland, in Ulster, flows nearly northwestward through the county of Fermanagh, and expands into two beautiful lakes, called Upper and Lower Lough Erne. After a course of 72 miles it enters Donegal Bay. The Lower Lough is 20 miles long, 7 miles wide, and over 200 feet deep. The Upper Lough is smaller. Each of them encloses numerous islands. The banks of these lakes and of the river present fine scenery. The town of Enniskillen stands upon an island between the loughs. On another island is the seat of the marquis of Ely. The loughs cover 40,000 acres, and are 140 feet above the sea. The salmon and other fisheries are very productive. The river and both loughs are deep, and have lines of steamboats, but the river has several cataracts.

Ernée, a town of France, in the department of Mayenne, 17 miles N. W. of Laval. It manufactures carpet-tacks and linseed oil, and trades in hemp, flax, and cloverseed. Pop. 5476.

Ernest (Ernst), elector of Saxony, the founder of the line called Ernestine or Ernestinian, was born Mar. 25, 1441. He succeeded his father, Frederick II., in 1464, and annexed Thuringia to his dominions in 1482. "This prince loved a quiet life, and sought it by all the means in his power, at the same time permitting no man to offend him with impunity." He did much for the development of the resources of his territories. Died Mar. 22, 1486.

Ernest (Ernst) I., surnamed the Pious, duke of Saxe-Gotha, born Dec. 24, 1601, at the castle of Altenburg, was a brother of the famous Bernard of Saxe-Weimar. In the Thirty Years' war he served with distinction under Gustavus Adolphus as a colonel of horse. He completed the victory of the Swedish army at Lützen, where Gustavus was killed. He was a zealous Protestant, and a ruler of great wisdom and activity. He instituted reforms, some of which were very fruitful of good. Many of his institutions exist to this day. Died in 1675.

Ernest (Ernst) IV., or **Ernst II.** of Saxe-Coburg-Gotha, duke of Saxe-Coburg, was born at Coburg June 21, 1817. His younger brother, Albert, married Queen Victoria of England. He succeeded his father in 1844, and sympathized with the efforts to promote the unity and nationality of the Germans. He composed operas entitled "Zayre" and "Casilda." In 1863 he declined the crown of Greece.

Er'nest Augus'tus, king of Hanover, born Jan. 5, 1771, was a younger son of George III. of England. He was styled the duke of Cumberland before he became king, and was a field-marshal in the British army. On the death of his brother, William IV., in 1837, he inherited the throne of Hanover, which was then separated from Great Britain, because it was not lawful for a woman to reign over Hanover. He was the object of intense popular dislike both in England and Germany. In the House of Lords he belonged to the extreme Tory party. In Hanover he was a tyrant, the unyielding defender of absolutism. He was generally considered, and with good reason, to be a man of grossly licentious habits. Died Nov. 18, 1851. He was succeeded by his blind son, George V., the last king of Hanover and the present duke of Cumberland.

Ernes'ti (August Wilhelm), a German philologist, born in Thuringia Nov. 26, 1733, was a nephew of the following. He became a good Latin scholar, and was professor of eloquence at Leipsic in 1770. He produced a good edition of Livy (3 vols., 1769) and other works, several of which were explanatory of the text of Livy's writings, and are still valued. Died July 20, 1801.

Ernesti (Johann August), a celebrated German critic and the founder of a school of theology, was born at Tennstedt, in Thuringia, Aug. 4, 1707. He was liberally educated at Wittenberg and Leipsic, and was so excellent a Latin scholar that he was called the "German Cicero." He became professor of ancient literature in the University of Leipsic in 1742, and obtained the chair of rhetoric in 1756, to which the chair of theology was added in 1758. In theology he was liberal or rationalistic. He proposed a new system of biblical criticism in his "Institutes of an Interpreter of the New Testament" ("Institutio Interpretis Novi Testamenti," 1761). He wrote other theological

works, and published an excellent edition of Cicero (5 vols., 1737–39), to which he added a "Clavis Ciceroniana." Died Sept. 11, 1781. (See A. W. Ernesti, "Memoria J. A. Ernesti," 1781; J. van Voorst, "Oratio de J. A. Ernesto," 1804.)

E'ros ['Ερως (gen. 'Ερωτος)], the Greek name of the god of Love, corresponding to the Cupi'do of the Romans. In Hesiod, Eros is one of the great cosmogonic powers, but later poets represent him as a son of Aphrodite (Venus). (See Cupid.)

Ero'sion [from the Lat. *e*, "out," "away," and *ro'do, ro'sum*, to "gnaw" or "eat"], a geological term used to express the action of a river in excavating or enlarging its channel, the gradual abrasion of strata, by rain, frost, glaciers, etc. The deep hollows occupied by most lakes and rivers are supposed to have been formed by the action of rivers or glaciers, and are called "valleys of erosion." The action of atmospheric agencies, glaciers, etc. in wearing away the general surface of a country or district is called *surface erosion* or *denudation*. The changes wrought by this agency on the superficial features of the earth are much more grand and interesting than they are generally supposed to be; and it may be said that the surface configuration of the earth, and indeed the whole "aspects of nature," are the result of the antagonistic action of surface erosion and internal elevatory forces. (See Surface Geology.)

Erot'ic [Gr. *ἐρωτικός*, from *ἔρως*, "love" (see Eros); Fr. *érotique*], an epithet applied generally to that which relates to love or excites amorous passion. In a more restricted sense it is applied to poems of which love is the subject, and to classic authors of whom love is the favorite theme, as Anacreon, Sappho, Ovid, and Tibullus.

Erpe'nius, or **Van Er'pen** (Thomas), an eminent Dutch Orientalist, born at Gorkum Sept. 7, 1584. He graduated at Leyden in 1608, after which he visited France, England, Italy, and Germany. In 1613 he became professor of Arabic and other Oriental languages at the University of Leyden. A second chair of Hebrew was founded for him in 1619. He printed a number of Arabic works with a press which he kept in his own house. He produced in 1613 an "Arabic Grammar," the first ever written in Europe. Among his other works are a "Collection of Lokmân's Arabic Proverbs," with Latin version, and "Historia Saracenica," which is an edition of Elmacin's history with a Latin translation (1625). Died in Nov., 1624.

Errard (Charles), a French painter and architect, born at Nantes in 1606. He was patronized by Louis XIV., for whom he adorned the Louvre, Tuileries, and other palaces. He was one of the twelve artists who founded the Academy of Painting in Paris in 1648, and was the principal founder of the French Academy of Art in Rome (1666). He died in Rome May 15, 1689.

Erra'ta [the plu. of the Latin *erra'tum*, a "mistake," from *er'ro, erra'tum*, to "err"], a term applied to the list of errors or faults committed in printing a book. This list is usually placed at the end or the beginning of the book.

Errat'ic Blocks, or **Erratics,** a geological term applied to fragments of rock which are found on the surface of the ground, and have been transported from a distance by glaciers, icebergs, etc. They are most numerous in northern regions. "The erratics which cover the Jura," says Lyell, "present a phenomenon which has perplexed the geologist for more than half a century. No conclusion can be more incontestable than that these angular blocks of granite, gneiss, and other crystalline formations came from the Alps, and that they have been brought for a distance of fifty miles across one of the widest and deepest valleys in the world." Many of them are as large as cottages. (See Drift.)

Er'roll, a post-township of Coos co., N. H. Pop. 178.

Ersch (Johann Samuel), a German bibliographer, born at Gross-Glogau, in Silesia, June 23, 1766. He became professor of geography at Halle in 1803, and published, besides other works, a "Handbook of German Literature from the middle of the Eighteenth Century" (4 vols., 1812–14) and a "General Repertory of Literature" (8 vols., 1793–1809). His capital work is the excellent "Encyclopædia of Sciences and Arts" ("Allgemeine Encyklopädie der Wissenschaften und Künste"), which he began conjointly with Gruber, and of which he edited seventeen volumes (1818–28). After his death, which occurred Jan. 16, 1828, it was continued by Gruber and others. He is called the founder of German bibliography.

Erse. See Gaelic Language.

Ers'kine (David Stewart), F. R. S., eleventh earl of Buchan, and Lord Cardross, born in 1742, a brother of Lord Chancellor Erskine, was the author of several antiquarian papers, "Lives and Writings of Fletcher of Saltoun and the Poet Thomson" (1792), and other works. He was a man of eccentric character. Died in 1829.

Erskine (Ebenezer), a Scottish preacher and the founder of the Secession Church, was born June 22, 1680. He preached at Portmoak, in Kinross, from 1703 to 1731, and acquired a high reputation. In 1731 he removed to Sterling, where he advocated popular rights in the settlement of ministers, and differed from the majority of the General Assembly in relation to lay patronage. He was deposed or suspended in 1733. In 1736, Erskine and his friends formally seceded and organized the Secession Church. Died June 22, 1756. In 1847 the Secession Church united with the Relief Church to form the United Presbyterians.

Erskine (Henry), an able Scottish lawyer, born in Edinburgh in 1746, was a brother of Thomas, Lord Erskine, noticed below. He was a Whig in politics, became lord advocate of Scotland in 1782, and again in 1806. He was eloquent and witty, and was distinguished for tact and fascination of manner. During some part of his career he was the most eminent member of the Scottish bar. Died in 1817.

Erskine (John), eleventh earl of Mar, a Scottish Jacobite and ambitious politician, was born at Alloa in 1675. He was appointed secretary for Scotland in 1708. In Sept., 1715, he took arms for the Pretender, and obtained the command of about 12,000 insurgents. He was defeated by the duke of Argyle at Dunblane in November of that year, and soon escaped to the Continent. Died in May, 1732.

Erskine (John), D. D., a Scottish divine, a son of the preceding, was born June 2, 1721. He was ordained minister of Kirkintilloch in 1744, and of Culross in 1753. In 1758 he was translated to the New Grey Friars' church, Edinburgh, where he became the leader of the orthodox and popular party in the Church. He was promoted in 1767 to the Old Grey Friars' church, where he was a colleague of Dr. Robertson, who was the leader of the moderate party. Erskine wrote many theological works, which are highly esteemed. Died Jan. 19, 1803. (See Sir H. M. Wellwood, "Life of John Erskine," 1818.)

Erskine (John) of Carnoch, an eminent Scottish jurist, born in 1695, was a son of Col. John Erskine and a grandson of Lord Cardross. He was appointed professor of Scottish law in the University of Edinburgh in 1737, and filled that chair until 1765. He published in 1754 "Principles of the Law of Scotland," and wrote an important standard work entitled "Institutes of the Law of Scotland," which was published in 1773. It is a work of high authority. Died in 1765.

Erskine (Ralph), a Scottish theologian, born at Monilaws March 18, 1685, was a brother of Ebenezer, noticed above. He was ordained minister of Dunfermline in 1711, and attained eminence as a preacher. In 1737 he joined the Secession Church. He was author of "Gospel Sonnets" and other religious works. Died Nov. 6, 1752.

Erskine (Thomas), Lord, a celebrated British orator and lawyer, born in Edinburgh Jan. 21, 1750, was the youngest son of Henry David, earl of Buchan. His father, whose income was about £200 a year, could not afford to give him a liberal education for a learned profession. Young Erskine therefore entered the navy in 1764 as a midshipman, after he had attended the High School of Edinburgh. Four years later he purchased a commission in the army, and in 1770 he married a daughter of Daniel Moore, M. P. In the social circles of London he was admired for his elegant manners, colloquial powers, and genial disposition. Renouncing the military profession, which he disliked, he resolved to study law, and was admitted as a student in Lincoln's Inn in April, 1775. In Jan., 1776, he entered Trinity College, Cambridge, as a gentleman commoner. It is said that in this part of his career he was very poor, suffered great privations, and boasted that he did not know a lord *out of his own family*. He was called to the bar in 1778, and obtained immediate and rapid success in his profession. One of his first clients was Capt. Baillie, prosecuted for a libel on Lord Sandwich, who was then a cabinet minister. He made his *début* in a court crowded with eminent men, yet when the judge interrupted him by the assertion that Lord Sandwich was not before the court, he had the courage to reply, "I know that he is not before the court, and for that reason I intend to bring him before the court." Lord Campbell expresses the opinion that Erskine's plea in this case was "the most wonderful forensic effort of which we have any account in our annals." In 1781 he defended Lord George Gordon, who was tried for treason and was acquitted. He was elected in 1783 to Parliament, in which his success was not so brilliant as in the forum. He was a Whig in politics, and was re-elected in 1790. In several political trials that occurred during the excitement of the French revolution he bravely defended the liberty of

the press and the friends of reform whom the ministers prosecuted on a charge of constructive treason. He was counsel for Mr. Hardy and Horne Tooke, who were tried in 1794 and were acquitted. On the formation of a Whig ministry by Fox and Grenville in Feb., 1806, he was appointed lord chancellor, and was raised to the peerage as Baron Erskine of Restormel Castle. He resigned this office when the Tories came into power early in 1807. He was the author of "Armata," a political romance, and a "View of the Causes and Consequences of the War with France," which ran through forty-eight editions. He died Nov. 17, 1823, leaving a son and several daughters. Many persons consider him the greatest advocate who ever practised at the English bar. "He spoke," says Lord Campbell, "as his clients respectively would have spoken, being endowed with his genius; and those who heard him seemed to be inspired with a new ethereal existence." His printed speeches, enriched with noble thoughts, brilliant imagery, and beautiful diction, retain in a great measure their original impressiveness. (See Lord Campbell, "Lives of the Lord Chancellors;" Lord Brougham, "Memoir of Erskine," prefixed to a collection of Erskine's speeches, 4 vols., 1847.)

Erskine (Thomas) of Linlethan, a member of the Scottish bar, who published several theological treatises, the best known and most valuable of which is "On the Internal Evidence for the Truth of Revealed Religion," 3d ed. Edinburgh, 1821.

Erskine College, at Due West, Abbeville co., S. C., was organized in 1839, with the Rev. E. E. Pressly (afterwards made D. D.) for its president, assisted by several professors, and belongs to and is under the supervision of the Associated Reformed Synod of the South. Although the college had to struggle with low salaries for professors, with the want of suitable buildings, libraries, and scientific apparatus, and other inconveniences, it had a reasonable share of prosperity for the first seven years of its existence. Dr. Pressly resigned the presidency in 1846, and was succeeded by the Rev. R. C. Grier, D. D. About 1853 the plan of endowing the college by the sale of scholarships was adopted, and the result was that some $50,000 were raised. These figures were enlarged afterwards by private donations of Capt. John Blair and Col. William Wright of Yorkville, S. C., and of Christopher Strong, Esq., of Tennessee, making the sum-total amount to $70,000. In the mean time four large and beautiful buildings were erected for college uses—the college proper, Lindsay Hall, the Euphemian and Philomathean Halls—while a fine telescope, the gift of William Johnson of Alabama, crowns the observatory. In 1858, Dr. Grier, finding that the presidency of the college and the pastorate of Due West congregation were too exacting on his time and ability, resigned the former, that he might devote himself more fully to the latter. In 1859 the Rev. E. L. Patton was elected president, but the war breaking out some two years afterwards, he resigned, soon after which the institution was suspended.

The college was re-opened at the close of the war under unfavorable auspices, the country being demoralized and private and public institutions impoverished. Dr. Grier was re-elected in 1867, and with the assistance of the professors and other friends succeeded in resuscitating the college. Unfortunately, however, he died in 1871, leaving a vacancy which was hard to fill. In September of that year the synod elected the Rev. William Moffat Grier to fill the place of his father. For the last few years the institution has subsisted chiefly on what is termed the "five years' endowment." Efforts are now being made to raise a new and more permanent endowment of $100,000, and if successful the institution will no longer be in a precarious condition.

The faculty now consists of the Rev. William M. Grier, D. D., president and professor of mental and moral science; Rev. J. P. Pressly, D. D., professor of Greek; Rev. J. N. Young, professor of mathematics and the natural sciences; William S. Lowry, A. M., professor of the Latin language; and William Hood, A. M., professor of chemistry, history, and belles lettres. William M. Grier.

Er'ving, a post-township of Franklin co., Mass., on the Vermont and Massachusetts R. R., 42 miles W. of Fitchburg. Pop. 579.

Er'win, a township of Steuben co., N. Y. It has extensive manufactures of lumber and other commodities, and contains the village of Painted Post. Pop. 1977.

Erwin (Alexander R.), D. D., a minister of the Methodist Episcopal Church South, born in Louisiana Jan. 12, 1820. His father was a Baptist minister. He was licensed to preach in 1840, and joined the Tennessee Conference in 1842. He occupied a high rank in the ministry, presided over the Clarksville Female Academy and the Huntsville Female College, and while stationed in Nashville received the degree of D. D. from the Nashville University. He died of consumption in Huntsville, Ala., Jan. 10, 1860. T. O. Summers.

Erysip'elas [Gr. ἐρυσίπελας, probably from ἐρυθρός, "red," and πέλος, akin to the Lat. *pellis*, "skin"], a disease probably of miasmatic origin, sometimes associated with a peculiar rose-colored eruption of the skin, whence the name. The inflammation attending this disease is of a peculiar low type which is but little understood. It may terminate favorably by resolution, less favorably by abscess (which is apt to be diffuse—*i. e.* not limited to a single spot—and is then very dangerous), or the termination may be in gangrene and the death of the patient. The disease is very common in military hospitals, seating itself in wounds, when it proves frequently fatal. Erysipelatous diseases sometimes assume an infectious and almost an epidemic character. Puerperal fever, peritonitis, phlebitis, and a long catalogue of diseases of low type are akin to erysipelas. Its infectious character is admitted. The famous old "Dreadnaught" hospital-ship in the Thames became so poisoned by it that she had to be destroyed. The best treatment is a sustaining one. Pure air, a milk diet, and the use of quinia and iron, with stimulants, are in general indicated. The sulphites and other disinfectant remedies may be employed. Externally, it is safest to use only the blandest applications, carbolized lotions, etc.

Erzgebirge, ĕrts-gā-beer'gā (*i. e.* "ore mountains"), a mountain-chain of Southern Germany, extends along the boundary between Bohemia and Saxony, and is nearly 120 miles in length. The Schwarzwald and Keilberg, the highest parts of this chain, have an altitude of about 4000 feet, and are of granitic formation. The Erzgebirge is rich in minerals, among which are silver, tin, iron, and cobalt. On the S. E. side it presents a steep, abrupt declivity.

Erzroom', Erzroum, or **Erzrum** [*i.e.* "land of Rome" or Byzantium, so called because it was originally founded under the Eastern Roman empire], a fortified town of Armenia (Asiatic Turkey), is on a fertile plain on the river Kara-Soo, a branch of the Euphrates, about 120 miles S. E. of Trebizond. It is about 6000 feet above the level of the sea. The streets are narrow and filthy; the houses are mostly built of mud, wood, or sun-dried bricks. It is the seat of an Armenian archbishop. It has a large citadel, a custom-house, about forty mosques, several Armenian and Greek churches, and a number of bazaars. Its position renders it an important military post. Erzroom has an extensive trade, which is carried on partly by caravans. Pop. estimated at 50,000, five-sixths of whom are Turks. A town called *Theodosiopolis* was founded here in 415 A. D. In 1201 it was taken by the Seljooks, who are said to have destroyed here 100 churches. In 1859 an earthquake destroyed a considerable portion of the town.

Esarhad'don [called in the cuneiform inscriptions *Asshur-akh-iddina*], the Old Testament name of an Assyrian king, the son and successor of Sennacherib. He appears to have reigned from 680 to about 667 or 660 B. C. He is shown by the monuments to have been one of the most powerful of Assyrian monarchs. His rule extended northward to Armenia, on the west it included Syria and Cyprus, while on the south Egypt, and even Ethiopia, were claimed by him. He built a palace at Babylon. Among the numerous and splendid remains of his reign is the south-west palace of Nimrood.

E'sau ("rough," "hairy"), the elder twin-brother of the patriarch Jacob (Israel), and the son of Isaac and Rebekah. He took his name from his hairiness of body. The story of his marriage to two Canaanitish and an Ishmaelite woman, of his loss of birthright through the craft of Rebekah and Jacob, and of his quarrel and reconciliation with Jacob, are beautifully told in the book of Genesis. He was the progenitor of the Edomites, who dwelt in Mount Seir, otherwise called Edom.

Escalade [Lat. *scala*, "ladder"], an operation of war, is an assault aided by ladders as the instrument of surmounting the obstacles presented by the scarp and counterscarp walls (or slopes) of a fortification in which no breach has been made; sometimes even a rapid blow directed at an unbesieged place with hope of success by surprise (*e. g.* the capture by the English troops of Almarez, Sept., 1812). Among the most famous escalades are those of Adrianople by the Goths; of Beauvais by Charles the Bold, in 1472; of Fecamp in 1593; of Prague in 1741: still more remarkable, that at Corfu in 1717 by Count Schulenberg, who, reduced to extremity in the defence by the capture of the outworks, hastily prepared ladders, and by a desperate assault by escalade, retook them, and thus saved the place. The second siege of Badajos (1812) presents an event unparalleled in the history of sieges, that after twenty days' open trenches and the opening of three practicable breaches,

two entire divisions of troops should, at the moment of assault, be employed to escalade the defences where entire; that each should *succeed*, while the regular assault on the breaches should be repulsed with terrible slaughter. The castle was successfully scaled where the walls were eighteen to twenty four feet high, and "tolerably flanked;" the Bastion St. Vincente had a scarp wall thirty-one and a half feet high, flanked by four guns, palisaded covered way, a counterscarp wall twelve feet high, and a "cunette" ditch five and a half feet deep. J. G. BARNARD, *U. S. Army*.

Escalop Shell, in heraldry, is a shell used to decorate palmers and crusaders, and signifies that the bearer has made long voyages by sea. The common name is scallop shell. The edible escalop of Europe (*Pecten maximus*) is considered a great delicacy. It belongs to the oyster family. The heraldic escalop shell, worn by palmers, belonged to the *Pecten Jacobæus*, which, as monkish writers assert, was the cognizance of Saint James the Great. The genus is very large and worldwide in distribution, there being more than 100 living and nearly 500 extinct species.

Escam'bia, a county in the S. of Alabama. Area, 1000 square miles. It is intersected by the Conecuh and Escambia rivers. The surface is level. Corn, rice, and wool are staple products. It is traversed by the Mobile and Montgomery R. R. Capital, Pollard. Pop. 4041.

Escambia, a county which forms the W. extremity of Florida, bordering on the Gulf of Mexico. It is bounded on the E. by the Escambia River and on the W. by the Perdido. The surface is level; some of the soil sandy, but a part is very fertile. There are extensive forests of pine and hard wood. Lumber, rice, wool, etc. are the chief products. It is traversed by the Pensacola and Louisville R. R. Capital, Pensacola. Pop. 7817.

Escanaw'ba, or **Escanaba,** a post-village, capital of Delta co., Mich., 360 miles N. of Chicago, on the N. end of Green Bay and on the line of the Peninsular division of the Chicago and North-western R. R. It has a savings bank, three churches, a blast-furnace, eight hotels, and one newspaper. It has a good harbor, and the principal business is shipping Lake Superior iron ores: upwards of 500,000 tons are sent yearly. Pop. of township, 1370.

CHARLES D. JEWELL, Prop. "TRIBUNE."

Escape, in law, means the departure of a prisoner from confinement before he has been released by process of law. Any liberty given to a prisoner not authorized by law is technically an escape. Escapes may occur either in civil or criminal cases. They are either negligent or voluntary—negligent, when the prisoner escapes without the consent of the officer having him in custody; voluntary, when such officer consents to the escape. In criminal cases an escape is a public offence, of which the prisoner may be convicted, as also the officer through whose act or neglect the escape occurs. In civil actions there is an important distinction between *mesne* and final process, the former being that which is issued between the commencement and the termination of the action; and the latter, that which is used to enforce the judgment. If the escape be voluntary, the officer is liable in either case; but if he be negligent, he will not be liable in the case of *mesne* process if the prisoner is returned to his custody before an action is commenced against him for his neglect; though he will be liable in any event in the case of final process. The damages recoverable are measured by the injury sustained. In final process these would in general be the amount of the judgment. Nothing will excuse an escape but an act of God or of the public enemy or of the law. An instance of the latter would be an order of the House of Representatives at Washington directing the attendance of a person as a witness who was held by a sheriff of a State court in custody under an execution in a civil action against his person.

Escapement, in watches and clocks, the device by which the rotatory motion of the wheels gives rise to or perpetuates the vibration of a pendulum or balance-wheel.

Escapements have received various forms, many of which are still in use. The earliest, introduced by Huyghens, about 1650, was called the crown-wheel or vertical escapement. The crown-wheel has its teeth not in the plane of the wheel, but in a cylindrical surface of which the axis of the wheel is the axis. In the crown-wheel of the clock or watch, the teeth were acute-angled, and inclined in a common direction like saw-teeth. The axis of the pendulum, or balance, was longer than the diameter of the crown-wheel over which it extended. It carried two short arms or projections, called pallets, set in different azimuths, in such a manner that when one of them, being encountered by a tooth, was pushed out of the way by the advancing wheel, the opposite one was caught by another tooth, which pushed in the opposite direction. Thus the wheel made an intermittent progress as the teeth successively escaped from the pallets.

In a clock, when the pendulum is disturbed from the mean position, it is brought back by gravity. In the watch the same result is produced for the balance wheel by the action of the spiral spring attached to the verge, called the hair spring. The escapement most commonly in use for both clocks and watches is the anchor escapement, first introduced by Hooke in 1656. It is so called from its resemblance to the flukes of an anchor, the shaft of the anchor in the clock being parallel to the pendulum and connected with it. The escapement wheel is a spur wheel. The pallets project from the extremities of the anchor flukes, meeting the wheel at the points where tangent lines from the centre of motion would touch it. When one pallet is engaged with the wheel, the other is free; and *v. v.* The extremity of the pallet is inclined in such a manner that, as the tooth escapes, it gives an impulse to the pendulum. As, after the pallet first engages a tooth, the swing continues for some time in the same direction, anchor escapements are of two kinds, according to the manner of their action upon the train during this swing. In Hooke's escapement, the surfaces of the pallets are so inclined that by their pressure on the tooth, they turn the train slightly backward, or cause it to *recoil*, up to the end of the swing. In the *dead beat* escapement, invented by Graham early in the last century, the surfaces of the pallets are circular arcs having the centre of motion for their centre; so that during the swing the train simply stands still. Though the dead beat escapement is now generally used in clocks, there are not wanting those who prefer the recoiling escapement. Besides the anchor dead-beat, there are several other very ingenious forms, among which may be mentioned Lepante's pin-wheel escapement, McDowall's ruby-disk escapement, and Denison's three legged dead escapement.

The only escapement used for watches till about 1700, was the crown-wheel escapement. Graham invented the cylinder escapement, so called because a hollow cylinder of steel or ruby replaces in part the verge of the balance. This cylinder is cut away on one side for about one-fourth of the circumference, in order to allow the pallets, which are small triangular pieces of steel, to enter the interior. During the swing the pallet rests with little friction on the smooth exterior or interior surface. In entering and in escaping, it gives an impulse to the balance. The pallet is not in the plane of the wheel, but stands on a short stem at right angles to this plane. Hence, the cylinder must be much more extensively cut away at the point where the wheel passes; and on this account, the cylinder escapement, though performing very well, is too frail to be popular in use. The duplex escapement of Lepine receives its name from having a double escapement. The escapement-wheel carries spur teeth rather widely separated, which engage at every double vibration with a notch in a cylinder forming part of the verge, and constructed of a gem. The verge itself carries also an arm which engages with a set of pins, or crown-wheel teeth, fixed in the escapement-wheel at right angles to its plane. The impulse is chiefly derived from the escapes of this arm, but proceeds to some extent from those of the spur teeth also. It takes place only in one direction, and hence the system is called by the French an escapement *à coup perdu*. The duplex escapement, though attended with little friction and running without oil, is subject to the disadvantage that a sudden jerk may check the swing of the balance and prevent the escape. If a single such failure occurs, the watch will stop.

The lever escapement is a dead-beat anchor escapement, first applied to the watch by Mudge, in 1793. The lever is attached to the anchor, generally crosswise, or at right angles to the proper position of the anchor-shaft. At one extremity it presents a notch into which a pin attached to the verge strikes at each swing in either direction. This tilts the anchor and allows a tooth to escape. Except at these moments of locking and unlocking, the balance swings entirely free. The lever carries also a pin just at the summit of the notch, which enters an indent in the verge as the lever passes. As there is no other indent, the lever cannot tilt except when the verge pin strikes it.

The escapement which interferes least with the uniformity of movement of the train, is the chronometer escapement, introduced into England about a century ago by Earnshaw, though said to have originated in France. In this, the train is locked by a tooth projecting from a light bar tangent to the escapement-wheel, which yields by bending and not by turning on a pivot, the fixed extremity being a spring. The free extremity carries another delicate spring parallel to itself and extending a little beyond it. A tooth on the verge passes this slight spring in one direction without sensible resistance. On its return the bar behind the spring prevents its bending, and so is carried along with it, unlocking the train. The train being released, a tooth of the escapement-wheel strikes a pin, or enters a notch, connected with the verge, and gives an impulse to the balance.

This, like the duplex, is an escapement *à coup perdu*, and is liable like that to stop when subjected to sudden jerks. Hence chronometers carried on the person sometimes stop; but with nautical chronometers this accident hardly ever occurs.

The chronometer escapement is sometimes called a free escapement; since the balance is wholly free from contact with any other part of the work, except in the instant of unlocking and receiving the impulse. This is true also of the lever escapement; but in that, the unlocking requires more force, and is attended with larger friction. (See CLOCK.)

F. A. P. BARNARD.

Escarp'ment, a geological term applied to the steep faces which are often presented by the abrupt terminations of strata, and resemble sea-cliffs. These have been caused by subaërial denudation, according to Lyell, who thinks the term escarpment "should be confined to the outcrop of particular formations having a scarped outline, as distinct from cliffs due to marine action."

Escataw'ba, a post-township of Washington co., Ala. Pop. 585.

Eschar, ĕs'kar [from the Gr. *ἐσχάρα*, "scurf," "scab"], a term applied to the slough caused by fire or caustics; the crust or scab, which is dry, rough, and of a gray color. (The word "scar" is supposed to have been derived from *eschar*.)

Eschatol'ogy [Gr. *ἐσχατολογία*, "doctrine respecting the last things"] is that section in dogmatics which treats of the second advent, the intermediate state, the resurrection, the last judgment, heaven, and hell. Upon these themes revelation does not go into minute details, while yet the salient points are strongly marked. The passages which must be relied upon to furnish the data are Matt. xxv., 1 Cor. xv., 2 Thess. ii., Rev. xx. and xxi.

As regards the second advent, the statement in the Apostles' Creed expresses the catholic faith. Christ "ascended into heaven, and sitteth at the right hand of God the Father Almighty; from *thence* he shall come to judge the quick and the dead." According to this symbol, which unquestionably presents the doctrine current in the primitive Church, there is no advent of Christ upon earth, after his ascension, until he leaves his session with the Father and comes directly to the final judgment of all mankind. This statement precludes millenarianism. According to this theory, there are two resurrections—the first of the righteous dead only at the time of the second advent of Christ, and the second that of the righteous and the wicked at the end of the world. Between these two resurrections a thousand years intervene, during which time Christ reigns personally, in corporeal presence, upon the renovated earth. Millenarianism was a revival of the later Jewish doctrine of the Messianic kingdom. Its most flourishing period was between 150 and 250 A. D. That it was not the general belief of the Church even then is proved by the above-quoted statement in the Apostles' Creed. Since that time it has had occasional advocacy, as by the Anabaptists of the Reformation period and the modern Millenarians.

The doctrine of the intermediate state has been somewhat fluctuating in its form, owing to the paucity of the Scripture data. The representation in the parable of Lazarus and Dives has furnished the basis of the general statement that the believer is happy and the unbeliever is wretched between death and the final judgment; yet the resurrection of the body adds somewhat to both the happiness of the believer and the misery of the lost. The majority of the ancient Fathers, in the opinion of Hagenbach, believed that men do not receive their full recompense of either reward or penalty until after the resurrection of the body. The doctrine of the intermediate state was soon vitiated, so far as the righteous dead are concerned, by the papal notion of purgatory; according to which the believer between death and the resurrection goes through a painful process that cleanses him from remaining sin. The Protestant rejects this, and affirms that at death the soul of a believer is made perfect in holiness. What precisely is the difference between the condition of a believer as disembodied and as re-embodied he does not affirm. He is content with denying purgatorial pains and purification, as well as an unconscious sleep of the soul between death and the resurrection.

The doctrine of the resurrection of the body was from the beginning a cardinal and striking tenet of Christianity. Perhaps no article of the new faith made greater impression at first view upon the pagan. When the philosophers of Athens "heard of the resurrection of the dead, some mocked, and others said, We will hear thee again of this matter." All the early Fathers maintain this dogma with great earnestness and unanimity against the objections of skeptics, of whom Celsus was acute and scoffing in his attack. Most of them believed in the resuscitation of the very same body materially. Justin Martyr says that cripples will rise as cripples, but at the instant of resurrection, if believers, will be made physically perfect. The Alexdrine school alone adopted a spiritual theory of the resurrection. Origen went so far in this direction as to assert that a belief in the resurrection of the body is not absolutely essential to the profession of Christianity, provided the immortality of the soul were maintained. But these idealizing views were generally combated with great earnestness, and in some instances evoked an extremely gross and carnal view in opposition. The Patristic theory of the resurrection passed into the Middle Ages with little variation, excepting that in connection with the materialism of the papacy it naturally became more materialistic in its structure. The poetry of Dante and the painting of Angelo powerfully exhibit it. In the Protestant Church the existence of a real body, and of a body that preserves the personal identity, is affirmed; but the materialism of the Papal, and to some degree of the Patristic, Church is avoided by a careful attention to Saint Paul's dictum: "There is a natural body (*σῶμα ψυχικὸν*), and there is a spiritual body (*σῶμα πνευματικὸν*)."

The doctrine of the last judgment was, from the first, immediately connected with that of the resurrection of the body. Mankind "must all appear before the judgment-seat of Christ, that every one may receive the things done in his body." 2 Cor. v. 10. The Fathers founded their views of the day of doom upon the representations and imagery of Scripture. They believed that a general conflagration will accompany the last judgment which will destroy the world, though some ascribed a purifying agency to it. Some of them, like Tertullian and the more rhetorical of the Greek Fathers, enter into minute details, while others, like Augustine, endeavor to define dogmatically the facts couched in the figurative language of the Bible. In the Middle Ages representations varied with the bent of the individual theologian. One popular opinion was that the judgment will be held in the valley of Jehoshaphat. Aquinas maintained that the last judgment will take place *mentaliter*, because the oral trial of each individual would require too much time. In the modern Church the course of thought upon this doctrine has been similar to that in the ancient and mediæval. The symbols of the different Protestant communions explicitly affirm a day of judgment at the end of the world, but enter into no description. Individual speculations, as of old, vibrate between the extremes of materialism and idealism.

That the blessedness of the redeemed is endless has been the uniform faith of the Church. Representations concerning the nature of this happiness vary with the culture and intellectual spirit of the age and the individual. Justin Martyr regards the blessedness of heaven as consisting mainly in the continuation and increase of the happiness of the millennial reign. Origen holds that the blessed dwell in the aërial regions, and pass from one heaven to another as they advance in holiness; at the same time he condemns those who expect merely sensuous enjoyment. The Greek theologians Gregory of Nazianzum and Gregory of Nyssa follow Origen. Augustine believed that the heavenly happiness consists in the enjoyment of peace which passes knowledge and the beatific vision of God. One important element in it consists in deliverance from all hazard of apostasy—the *non posse peccare et mori*. The Schoolmen held the Patristic theories, but with an endeavor to systematize. They divided heaven into three parts—the visible heaven, or the firmament; the spiritual heaven, where saints and angels dwell; and the intellectual heaven, where the beatific vision of the Trinity is enjoyed. The modern Church maintains the doctrine of everlasting blessedness in substantially the same form with the ancient and mediæval. The tendency to materialize or to spiritualize it varies with the grade of culture and modes of thinking.

The punishment inflicted upon the lost was regarded by the ancient Church as endless. The principal exception appears in the Alexandrine school, represented by Clement and Origen. But Clement is careful to say that the doctrine of endless perdition must be preached, in order to deter men from sin, although the hope of the final restoration of all is permitted to the thinker. Some faint traces of a belief in the remission of penalty in the future life are visible in the writings of Didymus of Alexandria. Gregory of Nyssa speaks more distinctly, pointing out the corrective design of punishment inflicted upon the wicked. The annihilation of the wicked was broached by Arnobius. The mediæval Church was likewise a unit in holding to the endlessness of punishment. The modern Church has also received the historical faith upon the subject, though recently a tendency appears in individuals and parties to the doctrine of a second probation and the final restoration of all mankind. The argument most relied upon is derived from the general nature of the Divine benevolence, rather

than from the testimony of Scripture. It is generally allowed, even by opponents, that the Bible, taken as a whole, apparently teaches the doctrine of endless punishment, and especially that the descriptions which Christ gives of the transactions and decisions of the day of judgment preclude the idea of a second probation. W. G. T. Shedd.

Escheat', a reverting of lands to their original owner (lord of the fee) because of some obstruction in the course of descent, either by failure of heirs or attainder of treason or felony; and the estate itself thus reverting is sometimes called an *escheat*. It differs from forfeiture in the fact that the latter is a penalty for a crime, and the property forfeited accrues to the king: while escheat depends solely on the failure of heirs, and the land reverts to the former proprietor. It was one of the incidents of the feudal system that when the heirs of the person last seized failed, the land reverted to the lord of the fee from whom it was derived. In this country, where the feudal tenure does not exist, the doctrine of escheat has a limited application; still, if an owner of land dies without heirs it escheats to the state. Incorporeal rights, such as ways and commons, do not escheat, but become extinct. It is still an unsettled question whether a trust estate will escheat by the death of the beneficiary without heirs, some authorities maintaining that the trustee is rather discharged from the trust. The land of a corporation, in case it becomes extinct, reverts to the grantor, and not to the state. The state takes an escheat subject to any charges or encumbrances attaching to the land when its title accrued. A proprietor may prevent an escheat by conveying or devising his estate. In this country the subject is generally regulated by statute.

Esch'enbach', von (Wolfram), a famous German mediæval poet or minnesinger, was born in Bavaria of a noble family. In the year 1204 he came to the court of Hermann, landgrave of Thuringia, whose bounty he enjoyed. He died after 1218 and before 1225. His principal poems are "Parcival" and "Titurel," which have been translated into modern German, and are much admired. They display a rich imagination and great mastery of language.

Esch'enmay'er (Karl Adolf), a German philosopher and mystic, born at Neuenberg, in Würtemberg, July 4, 1768. He became professor of philosophy and medicine at Tübingen in 1811, and obtained the chair of practical philosophy there in 1818. He wrote, besides other works, "The Philosophy of Religion" (3 vols., 1818–24). Died Nov. 17, 1852.

Esch'er (Johann Heinrich Alfred), a Swiss lawyer and statesman, born at Zurich Feb. 20, 1819, was liberal in politics. He opposed the Jesuits and the Sonderbund, was elected a member of the council of the interior in 1845, and became president of the grand council in 1847. He advocated a reform of the federal system and a greater centralization. In Dec., 1848, he was chosen president of the new council of regency.

Eschscholt'zia Califor'nica, the systematic name of a plant of the natural order Papaveraceæ, a native of California. It is cultivated for the beauty of its flowers, which are yellow. The calyx separates from the flower-stalk when the flower expands, and resembles the extinguisher of a candle. This genus was named in honor of J. F. Eschscholtz (1795–1831), a German botanist.

Eschwege, ĕsh-vā'gĕ, a walled town of Prussia, in the province of Hesse-Nassau, is on the river Werra, 26 miles E. S. E. of Cassel. It has a castle, a realschule, and manufactures of linen and woollen goods. Pop. in 1871, 7377.

Eschweiler, ĕsh'vī'lẽr, a town of Rhenish Prussia, is on the railway from Cologne to Aix-la-Chapelle, 8 miles by railway E. N. E. of the latter. It has extensive manufactures of ribbons, canvas, needles, glass, machinery, and woollen goods. Mines of zinc and lead occur in the vicinity. Pop. in 1871, 15,550.

Escobar' y Mendo'za (Antonio), a Spanish Jesuit and casuist, born at Valladolid in 1589. He wrote "Moral Theology" (1646), "Summula Casuum Conscientiæ" (1626), and other works. The lax morality of his writings was censured by Pascal in some of his "Provincial Letters." Died July 4, 1669.

Escosu'ra, de la (Patricio), a Spanish author, was born in Madrid Nov. 5, 1807. He was banished as early as 1824 on account of his connection with a secret political society. In 1826 he returned and joined the army, after having studied in Paris and London. In 1829 he became an officer, and joining the Carlists was exiled in 1834, but returned in 1835. Having been again banished, he was made secretary of state (in 1843) under Narvaez, and minister of the interior. Besides several novels, plays, and poems, he published a "Constitutional History of England" (1859), "Artistic and Monumental Spain," and other works.

Escrow, a deed deposited by a grantor with a third person, to be delivered to the grantee on the happening of a certain condition. Until the condition is fulfilled and the escrow delivered, it has no effect as a deed, and the title of the estate remains in the grantor. It takes effect, in general, as a deed from the second delivery. Where the ends of justice require it, it may be referred, for its validity by a fiction of law, termed "relation," back to the first delivery.

Escu'rial, or **Esco'rial** [Sp. *escorio*, "dross," applied to all places where there are old or exhausted mines], a monastery and royal palace near Madrid, in Spain, built by Philip II., and dedicated to Saint Lawrence on occasion of the victory of St.-Quentin in 1557, on that saint's day. It is whimsically built in the form of the gridiron on which that saint is said to have been broiled alive. The work was begun by Juan Bautista de Toledo in 1563, and completed by his pupil, Juan de Herrara, in 1584. The cross-bars of the gridiron are represented by ranges of buildings separated by intervening courts, and which were formerly inhabited by monks and ecclesiastics. The main portion of the building is 740 Spanish feet long, and 580 in breadth. The projection which forms the royal palace is 460 feet in length. The height of the edifice is about sixty feet, and at each angle is a square tower 200 feet high. It is one of the largest and perhaps one of the most tasteless buildings in Europe, though grand from its size. The church in the centre of this enormous mass of stone is very large and rich. The Pantheon, a repository beneath this church, is the place of interment for the royal family, whose remains are deposited in tombs of marble placed in niches, one above another. The richest part of this edifice, however, was that which contained the valuable pictures, and which altogether formed the best collection of the productions of the first masters that any place in Europe displayed. The French, when in possession of the Escurial, removed many of its best treasures, which included the finest productions of Rubens, Titian, Spagnoletto, Raphael, Baroccio, Velasques, Murillo, and others. The most valuable treasures of the Escurial, however, are the immense collection of ancient manuscripts preserved in the library, especially those of the Arabian writers. (*Encyc. Brit.*) In 1872 it was fired by lightning, suffering some damage.

Escutch'eon [Fr. *écusson*, from the Lat. *scutum*, a "shield"], a heraldic term applied to a shield on which arms are represented. The points of the escutcheon are nine in number, being the parts named in order to express the local position of the charges borne on the field. An escutcheon of pretence is the shield on which a man carries the arms of his wife, if she is an heiress and has children. It is placed in the centre of his own shield, and is mostly of the same form.

Escutcheon, or **The Milk Mirror,** in the Guénon method of selecting milch cows, is the shield-like outline upon the back of the cow's udder and the adjacent parts, formed by the upward growth of the hair. Some writers call the whole outline the "mirror," and the upper part only the "escutcheon." It is found by careful observation that the size and perfection of these marks afford valuable means of judging of the milking qualities of cows, though much experience is required in learning to make the estimate. (See C. L. Flint, "Milch Cows and Dairy Farming," 1859.)

Esdrae'lon, in the apocryphal book of Judith, **Esdrelon** [from the Gr. Ἐσδραηλά, a corruption of the Hebrew *Jezreel*], the most picturesque, most fertile, and historically most important plain in Palestine, "lying between Tabor and Carmel, and between the hills of Galilee on the north and those of Samaria on the south." In Scripture it is twice (2 Chron. xxxv. 22; Zech. xii. 11) called "the valley (plain) of Megiddo." Jezreel is properly the south-eastern part of it, although this name is sometimes given to the whole. It is triangular in form, the length of its south-eastern side being about 15 miles, its south-western about 18 miles, and its northern about 12 miles. Its surface, whose elevation is about 400 feet above the Mediterranean, is slightly undulating. It sends off towards the Jordan three great arms or branches, which are separated from each other by the mountains of Gilboa and Little Hermon. Only one of these arms, however (the middle one), declines eastward. The greater part of the plain is drained by the Kishon, which empties into the Mediterranean near Acre. This great plain has been the scene of several important battles, and with it are associated the names of Barak, Gideon, Saul, Josiah, and Napoleon. (See Robinson, "Physical Geography of the Holy Land," 1865.)

Es'dras, Books of, are certain books of the Old Testament and of the Apocrypha ascribed to Ezra, whose name is Græcised into *Esdras*, following the Septuagint. The canonical books of Ezra and Nehemiah (as they are called in the authorised English version) are denominated in the

Vulgate and in the Thirty-nine Articles of the Anglican Church the first and second books of Esdras, while the apocryphal books, now generally known as the first and second of Esdras, are there called the third and fourth of Esdras. The Geneva Bible (1560) first adopted the present nomenclature, calling the two apocryphal books first and second Esdras.

The first (apocryphal) book of Esdras was written in very good Greek, but whether in Palestine or in Egypt, and at what time, cannot be determined. It is not without historical value, and is for the most part a history of the restoration of the Jews after the Babylonian captivity. It is not received into the canon of either Jews or Christians.

The second apocryphal book of Esdras is purely pseudepigraphic, being a record of pretended revelations made to Ezra for the encouragement of the suffering Jews. Many interpolations have been made to it by some over-zealous Christian. The original is believed to have been written by a Jew of Egypt in the Greek tongue, either just before or soon after the Christian era. The original Greek is lost, but Latin, Ethiopic, and Arabic versions exist. It is canonical in the Abyssinian Church. English versions are the authorized, from the Latin, Ockley's, from the Arabic (1711), and Laurence's, from the Ethiopic (1820).

Esk, a small river of Scotland, in the county of Dumfries, flows southward through Eskdale Muir, and enters Solway Frith. Length, about 40 miles. Its valley is noted for picturesque scenery. Another river Esk is formed by the union of the North and South Esk, which meet in Dalkeith Park, Edinburghshire. It enters the Frith of Forth at Musselburgh.

Esk'ee Sa'ra, or **Eski Sagra,** a town of European Turkey, province of Room-Elee, on the south slope of the Balkan Mountains, 70 miles N. W. of Adrianople. It has manufactures of carpets, coarse linen, and leather. Here are several mineral springs. Pop. estimated at 18,000.

Eskilstuna, a Swedish town, 55 miles W. of Stockholm. It is the principal place for the manufacture of the better sorts of iron. Pop. 5088.

Eskridge, a thriving post-village of Wabaunsee co., Kan., near the centre of the county, has one weekly newspaper.

Es'men, a township of Livingston co., Ill. Pop. 917.

Esmeral'da, a county in the S. W. of Nevada, bordering on California. The surface is mountainous; the soil is sterile except along the streams. It contains Walker's Lake, which is about 30 miles long and has no outlet. Silver-mines have been opened in several parts of the county. Gold, copper, iron, salt, lead, and mercury are found. Cattle and grain are raised. Capital, Aurora. Pop. 1553.

Es'neh, Esné (anc. *Latopolis*), a town of Upper Egypt, on the left bank of the Nile, about 30 miles above Thebes. It has manufactures of blue cotton and pottery; also an active trade with Sennaar and Abyssinia. Here are the ruins of the populous ancient city of *Latopolis*, so called from the worship of the *latus* fish. Among them is a well-preserved portico of a grand temple, with twenty-four beautiful columns standing, and a zodiac on the ceiling like that at Denderah. All the rest of the temple is literally buried, the houses of the modern town standing even upon its roof. In visiting the portico, one goes down as into a deep vault. It was cleared of rubbish by order of Mohammed Ali in 1842. An older temple appears to have been built there by Thothmes III. of the eighteenth dynasty, but the present edifice dates from the times of Tiberius, Vespasian, Trajan, Hadrian, and Antoninus. On the river-bank are also the remains of a Roman quay. Pop. 12,000.

Esop. See Æsop.

Eso'pus, a post-township of Ulster co., N. Y. It contains Port Ewen and other villages, produces much ice, fruit, and hydraulic cement, and is a place of summer resort. It takes its name from a tribe of Algonkin Indians long since extinct. Pop. 4557.

Esoteric, ĕs-o-tĕr'ik [from the Gr. *ἐσωτερικός*, "inner," "intimate"], a term applied to those doctrines which are designed for the initiated only. The ancient philosophers are supposed to have had a set of mysterious doctrines, which they imparted to their more enlightened and intimate disciples, and other doctrines, more popular, for the benefit of the multitude. This opinion is to some extent well founded as regards Aristotle, except so far as relates to the suspicion of intentional concealment, which is implied. His exoteric or published writings appear to have been written as dialogues, and are not extant. His esoteric works, as may be inferred from the synonymous term *acroamatic*, were not intended to supersede the necessity of oral instruction to render them intelligible, and this may account for the perplexed arrangement, brevity, and repetitions of his surviving works.

E'sox, a genus of fishes which includes the pikes, and the type of the family of the Esocidæ. These are the most voracious of all fresh-water fishes, attain a large size, and live to a great age. The habits of the European pike (*Esox lucius*) have been often described. In North America there are many species of the genus *Esox*, of which the largest and finest is the muskallunge (*Esox Estor*). The pickerel (*Esox reticulatus*) is perhaps the most common and best known of our pikes.

Esox lucius.

Espalier [Fr.], in horticulture, a railing or trellis-work used as a substitute for a wall, on which to train fruit trees or ornamental shrubs. The objects are to hasten the ripening of fruit by exposing the foliage of the plants more freely to the light, to prevent the branches from being blown about by the winds, and to economize space. The espalier is constructed of wood or iron, and consists of horizontal rails supported by upright posts. Apples, peaches, and pears are trained on espaliers in England.

Esparte'ro (Joaquim Baldomero), duke of Vittoria, was born Feb. 27, 1792, at Granatula, La Mancha. He was the son of a cartwright. He enlisted in the army in 1808, served as an officer against the French, against Bolivar (1815–25), and against the Carlists (1833–40). He became a lieutenant-general in 1835, a grandee in 1838, regent of Spain in 1841, was banished by Narvaez in 1843, and became prime minister in 1854. Under King Amadeus (1872) he was senior captain-general of the army. (See J. S. Florez, "Espartero: Historia de sa Vida," 3 vols., 1844.)

Espar'to (*Sti'pa* or *Macroch'loa tenacis'sima*), a species of grass growing in Spain, Barbary, etc., has a very strong fibre, which is used by the Spaniards for making cordage, mats, nets, etc. Large amounts are used in Great Britain in the manufacture of paper. Its culture in the U. S. has been recommended. Esparto, the *halfa* of Algiers, was first used for paper by an Englishman named Routledge, whose patent was issued in 1846. The paper produced is generally of good quality.

Es'perance, a post-township of Schoharie co., N. Y. Pop. 1276.

Espinasse, de l' (Claire Françoise, or Julie Jeanne Éléonore), a fascinating French lady, born in Nov., 1732. She was distinguished for her imagination and sensibility. In 1752 she went to live in Paris as companion to Madame du Deffaud, in whose house she remained nearly ten years. She gained the affection of D'Alembert, and became about 1762 mistress of a *salon* which was frequented by a brilliant literary coterie. Died in May, 1776. Her published letters are much admired.

Espinasse (Esprit Charles Marie), a French general, born at Saissac, in Aude, April 2, 1815. He served in the Crimean war as a general, and distinguished himself at the Tchernaya (1855). In 1858 he was minister of the interior for about four months. He was killed at the battle of Magenta June 4, 1859.

Espinel' (Vincente), a popular Spanish poet, born at Ronda about 1544. He learned several ancient and modern languages, and became a priest. It is stated that he served some years as a soldier, and led an adventurous life in several foreign countries. Among his works are numerous songs, the "House of Memory" ("La Casa de Memoria"), and a novel entitled "Marcos de Obregon" (1618), from which Le Sage borrowed incidents of "Gil Blas." Espinel ranked among the best poets of his time. Died in 1634.

Espinha'ço, Ser'ra do, a mountain-chain of Brazil, in the provinces of Bahia and Minas Geraes. It contains diamond-mines.

Espir'ito San'to (*i. e.* "Holy Spirit"), [Port.], a province of Brazil, is bounded on the N. by Bahia, on the E. by the Atlantic, on the S. by Rio Janeiro, and on the W. by Minas Geraes. It is partly drained by the Rio Doce. The soil is very fertile, but a large part of the province is still covered with forests, in which are many valuable woods and drugs. The lowlands along the coast produce sugar, cotton, rice, and manioc. Capital, Vittoria. Pop. 65,000, of whom 15,000 are slaves.

Espiritu Santo [Sp.], a town of Cuba, near the middle of the island, about 240 miles E. S. E. of Havana. Pop. about 10,000.

Esplanade, ĕs'plan-ād' in fortification, is an open

space of ground left between the glacis of a citadel or fort and the houses of a town, in order to prevent the enemy erecting breaching-batteries under cover of buildings. The term has also been applied to the glacis of the counterscarp, or the slope of the parapet of the covered way towards the country.

Es'py (James P.), an American meteorologist, styled the "storm-king," born in Washington co., Pa., May 9, 1785. He was the author of a theory of storms which excited some controversy, and which he published in 1841, in systematic form, under the title "The Philosophy of Storms." According to this theory, every great atmospheric disturbance commences with the uprising of a body of air which has been rarefied by heat. The heavier air, flowing in beneath, creates currents converging from all directions to the central point. The rising mass dilates as it rises, in consequence of diminished pressure, and its temperature falls, in consequence of this dilatation, down to the dew-point and below, precipitating its contained vapor in the form of cloud. The latent heat of elasticity thus liberated dilates the air still more, and disturbs the equilibrium anew, so that the rising continues to go on, till the moisture in the air forming the upward current is practically exhausted. As the heavier air flowing in beneath finds a diminished pressure above it, this air also rises, causing still greater drafts upon the surrounding air, and establishing permanent converging currents, which meet in the centre and rush upward, with constantly increasing violence. The vast amount of aqueous vapor precipitated during this atmospheric commotion gives rise to heavy rains. Mr. Espy's theory found many adherents. The physical principles on which it rests are sound, and it is so far supported by observation. It received also the approval of the French Academy of Sciences in a formal report. But his views as to the mechanics of storms are untenable, and are contrary to observed facts. Converging currents invariably produce rotation, and hence, though storms doubtless often originate in the causes assigned by him, their characteristic action is rotatory or spiral. A lively controversy was for some time maintained between the supporters of Mr. Espy and those of his principal opponent, Mr. Redfield, who held the rotatory theory. This long ago ceased, and the rotatory theory is now generally accepted. It has given to meteorology the familiar term *cyclone*. It has also been made the basis of instructions, for the use of navigators, by the British Admiralty and the U. S. bureau of navigation.

Mr. Espy entertained a sanguine belief that rains could be brought on at any time by means of great fires, kept up long enough and over a sufficiently large surface to initiate a powerful upward movement, relying on natural causes to maintain the current when once started. He even supposed that it might be possible in this way to maintain the navigation of the upper Ohio River through the dry season. He therefore petitioned Congress and the legislature of Pennsylvania to make a sufficient appropriation to enable him to try the experiment; but without success. He received, however, an appointment as meteorological observer under the government; and while holding this position he made arrangements, in accordance with a judicious suggestion of the Hon. A. H. Stephens of Georgia, with the press and with the various lines of telegraph converging to the capital, to publish daily bulletins of the state of the weather in different and distant localities. These were doubtless the first weather-telegrams ever regularly made public. The system, discontinued during the war, has been since revived and largely extended. It has also been introduced into England and into parts of continental Europe. While enjoying its benefits the world should not forget the meritorious observer with whom it originated. He died in Cincinnati Jan. 24, 1860. F. A. P. Barnard.

Esquimaux, es'ke-mo' (plu.), [a French orthography of the Algonquin *eskemo*, an "eater of raw flesh;" called in their own tongue *Innuit*, "men"], a race of men inhabiting the Arctic coasts of North America and its islands, and the coast of Labrador nearly as far south as the Gulf of St. Lawrence; also found on the extreme north of the Pacific coast of Alaska, and to some extent in the N. E. part of Asia. They are short, though broad and muscular, very seldom exceeding five and a half feet in height. In color they are of a rather light brown, and in features they approach the Mongolian type. Their food consists of the flesh of whales, seals, the walrus, birds, and fish. They have remarkable skill in fishing and hunting. Their only domestic animal is the dog, of which they possess a large and powerful variety, very useful to them, not only in the chase, but for drawing sledges. Their personal habits are extremely filthy. Their dress is made of skins, and is nearly the same in both sexes. Their religion is a rude superstition, in which only the vaguest notions of a Supreme Being can be found. In Greenland and on the Labrador coast the Moravian and the Danish Lutheran missionaries have, since 1721, brought to many of them the knowledge of Christianity.

The ethnological relations of the Esquimaux are not well understood. Physically, they approach the Mongolian type, and their presence in Asia would appear to confirm this view of their origin, but their language is of the American structure and inflection. There appears to be a remarkable uniformity in their vocabulary throughout the whole race. The opinion of Pritchard, that they are a link in the chain connecting the Mongolian and the American races, seems to be the prevailing belief with ethnologists. Their numbers in America are estimated at 47,500, of whom about 20,000 are in Greenland, 1500 in Labrador, 4000 on the coasts of Hudson's Bay, and 17,000 in Alaska. (See Monté-mont, "Mœurs et Coutumes des Esquimaux," 1841; C. F. Hall, "Life with the Esquimaux," 1864.)

Esquire [from the Sp. *escudero* (*i. e.* a "shield-bearer"); Old Fr. *escuyer*], a name originally given to an armor-bearer, an attendant on a knight. As this office in times of chivalry was mostly borne by persons of good family, the word esquire came to be used in England for the rank next below knight and above simple gentleman. The younger sons of peers, who are now called honorables, their eldest sons, and those of knights, the justices of the peace, sheriffs of counties, sergeants-at-law, and doctors of divinity, are esquires by virtue of their rank or office. Heads of ancient families are esquires by prescription, and hence the word has come to be used as a common addition to the names of all who hold the rank of gentleman. An esquire was formerly created by the king by putting a silver collar of *SS* around his neck and bestowing on him a pair of silver spurs.

Esquirol (Jean Étienne Dominique), M. D., a French physician and philanthropist, born at Toulouse Jan. 4, 1772. He founded at Paris in 1799 an asylum for the insane, which was a model institution, and he initiated a reform in the treatment of the insane. In 1817 he began a course of clinical lectures for mental maladies, on which he wrote a valuable work, "Des Maladies Mentales" (2 vols., 1838). He became in 1826 chief physician of the asylum at Charenton. Died Dec. 12, 1840.

Esquiros (Henri Alphonse), a French poet and novelist, born in Paris in 1814. On account of his work, "The Gospel of the People," he was in 1840 sentenced to eight months' imprisonment, during which time he became an intimate friend of Lamennais. After the revolution of 1848 he was elected a member of the Legislative Assembly, in which he belonged to the extreme Left. In consequence of the *coup-d'état* of 1851, he had to leave France, and lived in England until 1869, when the amnesty proclaimed by Napoleon allowed him to return. Soon after he was elected a member of the Legislative Body. After the overthrow of the empire, in Sept., 1870, the provisional government sent him as administrator-general of the department of Rhone to Marseilles, where he succeeded in suppressing anarchical tendencies. He favored the separation of the south of France from the north, and for a while refused to recognise the decree of Gambetta which suspended him, but finally resigned in Nov., 1870, in order to avoid a civil war. In Feb., 1871, he was elected a member of the National Assembly, and took his seat at the extreme Left. He published, besides other works, "The Magician" (1837), "Charlotte Corday," a novel (1840), "The Gospel of the People" ("Évangile du Peuple," 1840), "The History of the Mountain" ("Montagnards," 1847), "La Morale Universelle" (1859), "l'Angleterre et la vie anglaise" (5 vols., 1859–70); and in the English language, "Religious Life in England" (London, 1867), "English Seamen" (1868).

Ess, van (Leander), a German Catholic theologian, distinguished at once for his learning and his liberality of opinion, especially with respect to the circulation of the Scriptures, was born at Warburg, in Westphalia, Feb. 15, 1772. In 1790 he entered the Benedictine monastery of Marienmünster in Paderborn, in 1796 became priest, afterwards pastor at Schmalenberg, and in 1813 professor extraordinary of theology at Marburg. He aided his cousin, Karl van Ess (1770–1824), in publishing a German translation of the New Testament (1807), and twelve years later (1819), without assistance from his cousin, who had meanwhile given up his liberal opinions, published also a translation of the Old Testament. His edition of the Vulgate appeared in 1822, and his edition of the Septuagint in 1824. He lived in seclusion for several years, and died Oct. 13, 1847. His library, rich in Bibles, patristic, mediæval, and Reformation literature, and making some 18,000 volumes, now belongs to the Union Theological Seminary in New York City.

Es'say [Fr. *essai*], an attempt; an experiment: a lit-

erary composition. In literature this title is generally given to short disquisitions on subjects of taste, philosophy, morality, etc. In this sense it has been applied to periodical papers published at regular intervals under a collective name by one or more writers. From the appearance of the "Tatler," which was chiefly written by Sir Richard Steele, this species of literature continued to be a favorite in England for seventy years. Many series of essays were produced, the best of which are united in one collection under the name of "The English Essayists." The most celebrated of these writings was "The Spectator," to which Addison contributed the best essays; and next to it the "Rambler," chiefly written by Dr. Johnson. Among the eminent essayists of more recent times is Macaulay. The title of *essay* has been also adopted by way of indicating diffidence in the completeness of their work by authors of more extended performances, as by Locke, "Essay on the Human Understanding."

Essek. See Eszek.

Es'sen, a town of Rhenish Prussia, on the Cologne and Minden Railway, and near the river Ruhr, 27 miles by railway N. E. of Düsseldorf. It has a cathedral, a gymnasium, a realschule, and a female high school; also manufactures of steam-engines, firearms, woollen cloth, paper, and iron wares. It derives its prosperity chiefly from the rich coal-mines which surround it. In the vicinity is a large iron-foundry, copper-mills, and Krupp's extensive manufactory of steel. Pop. in 1871, 51,526.

Es'sen (Hans Henrik), Count of, a Swedish general, born in West Gothland in 1755. He was appointed governor of Stockholm in 1795, and obtained in 1807 the command of an army with which he defended Stralsund against the French. He was sent as ambassador to Paris by Charles XIII., who became king in 1809. In 1814 he was raised to the rank of field-marshal and governor-general of Norway. Died July 28, 1824.

Essence, a solution of an essential oil in alcohol or rectified spirit. (See Essential Oils.)

Es'sence [Lat. *essen'tia*, from *esse*, "to be," literally, "being"]. Chauvin, in his "Lexicon Rationale" (1713), gives the following definition of this word: "All that by virtue of which anything is, and is what it is." The "essential qualities" of an object or being consist of those elements each and all of which are necessary to its existence. The term essence is used to denote the sum of these essential qualities. The term is used as a general name for the essential qualities or elements of all objects or beings in general, or to denote similar elements in a single object or being. Much confusion in thought arises from the failure to distinguish between the general and singular use of this term and the closely allied word *substance*. By the modern Platonists the word is used to denote the real being, "idea," or spiritual substance of objects, as distinguished from the matter which represents the "idea" to the outward senses. The Scholastics, who adopted the Aristotelian distinction of "matter" and form, departed somewhat from the Aristotelian conception, and called the matter of any object its substance, and the "form" or force which shaped the matter and determined its genus or species, the essence of the object, as made up of all those modalities without which the object, as such, would cease to exist. This mode of statement was specially adopted by the Scotists. Descartes so defined substance that the term was applicable to God only, and denominated by essence all those forms of matter which determine species and genera, and without which they would cease to be. The words *essence* and *substance* in modern writers are often used as substantial synonyms, denoting all that in any object the knowledge of which is impossible to the human mind; while quality or accident is used to name all that can be actually known. Few terms in philosophy and theology are used with more confusion and vagueness. It is always requisite in reading discussions in which they frequently occur to ascertain the exact or inexact sense in which an author uses them.

Essenes, ĕs-seenz' [Gr. Ἐσσηνοί; Lat. *Esse'ni*], or **Essæans** [Gr. Ἐσσαῖοι], the latest, and apparently the smallest, of the three Jewish sects in existence in the time of Christ. They are not mentioned in the New Testament. The etymology of the name is doubtful, and the history of the sect obscure. The Essenes were mystics, and most of them celibates. They are not to be confounded with the Therapeutæ, although a kindred sect. The greater part of them lived by themselves near the N. W. shore of the Dead Sea, but they were also scattered in various parts of Palestine, and are supposed to have numbered in all some 4000 or 5000. The first distinct trace of them is about 110 B. C., and they disappear from history after the destruction of Jerusalem by the Romans. (See Jewish Sects.)

Essen'tial Oils [so called because they were formerly supposed to contain the essence or active principle of the plant or substance from which they are extracted], called also **Vol'atile Oils,** a large class of compounds, mostly of vegetable origin, though some are derived from animal sources. They mostly exist already formed in plants. With a few exceptions they are colorless, and have in most cases a powerful odor and pungent taste, resembling that of the plant whence they are derived. A large number of them are isomeric (or identical in composition) with oil of turpentine and with caoutchouc. These are called terpenes ($C_{10}H_{16}$); others are aldehydes; still others appear to be compounds of alcohol radicals with organic acids, etc. A very few contain sulphur. Most of them are obtained by distillation with water, others by pressure. They are in many cases changed by time and exposure into resins, or resolved into several distinct substances.

Essequi'bo, a river of British Guiana, rises near the S. frontier, flows northward through forests of gigantic trees, and enters the Atlantic by an estuary 20 miles wide; lat. 7° 0′ 20″ N., lon. 56° 42′ 31″ W. Length, 500 miles. It is navigable 60 miles.

Es'ses, Collar of, or **Collar of *SS*,** a heraldic ornament composed of *S*-shaped links joined together or embroidered somewhat after the manner of a chain. It enters into the insignia of various officers in England, and was, it is said, anciently worn by all esquires. It is claimed by some that the *SS* is emblematic of Saint Simplicius.

Es'sex ["East Saxons"], a county of England, bounded on the E. by the North Sea and on the S. by the estuary of the Thames. Area, 1657 square miles, of which nine-tenths are arable. It is partly drained by the Stour, the Lea, and the Chelmer rivers. The surface is pleasantly diversified, except the flat marshy land near the sea. The soil is mostly a fertile loam, which produces wheat, barley, oats, beans, hops, potatoes, etc. Essex is an agricultural county, having comparatively few manufactures. Many sheep are raised. The chief towns are Chelmsford (the capital), Colchester, Harwich, and Maldon. Essex was a kingdom of the Anglo-Saxon Heptarchy, which comprised Essex and parts of Middlesex, Hertford, and Bedford. Pop. 466,427.

Essex, a county which forms the S. W. extremity of Ontario, Dominion of Canada. Area, 677 square miles. It is bounded on the N. by Lake St. Clair, on the S. by Lake Erie, and on the W. by Detroit River. The soil is productive. It is intersected by the Great Western Railway. Capital, Sandwich. Pop. in 1871, 32,697.

Essex, a county which forms the N. E. extremity of Massachusetts. Area, 500 square miles. It is bounded on the E. by the Atlantic Ocean and on the S. E. by Massachusetts Bay. It is intersected by the Merrimack River, and has several good harbors on the coast. The surface near the sea is rugged and rocky, but the soil is generally fertile. Fruit, hay, grain, and garden and dairy products are raised extensively. The inhabitants of Gloucester, Marblehead, Beverly, Salem, and Newburyport are extensively employed in commerce and the fisheries. Essex county is traversed by the Boston and Maine, the Essex, the Eastern, and the Newburyport R. Rs. Here are extensive manufactures of carriages, leather, shoes, machinery, cotton, linen, wool, and many other goods. Lawrence, Lynn, Haverhill, Salem, Marblehead, Peabody, Gloucester, Newburyport, Andover, Amesbury, and Danvers are large and important towns. Ice and granite are largely exported. Capitals, Salem, Newburyport, and Lawrence. Pop. 200,843.

Essex, a county in the N. E. of New Jersey. Area, about 130 square miles. It is bounded on the E. by the Passaic River and Newark Bay, and on the W. by the Passaic River. The surface is nearly level, except the western part; the soil is productive. Hay, grain, dairy and garden produce are raised extensively. The manufactures include boots, shoes, metallic wares, saddlery, carriages, and a great variety of commodities. It is intersected by the Morris and Essex, the Paterson and Newark, and the New Jersey R. Rs.; also the Morris Canal. This is the most populous county in the State. Capital, Newark. Pop. 143,839.

Essex, a county in the N. E. of New York. Area, 1926 square miles. It is bounded on the E. by Lake Champlain, and contains several small lakes. The Au Sable River forms part of the northern boundary of the county, which is partly drained by the Hudson River. The surface is mountainous, and mostly covered with forests. Essex county comprises a large part of the Adirondac Mountains, and Mount Marcy, the highest point in the State, here rises 5467 feet above the level of the sea. Among its mineral resources are iron ore and limestone. Potatoes, grain, wool, hay, and dairy products are raised extensively. Lumber, leather, cooperage, iron, and starch are among

the manufactured commodities. Capital, Elizabethtown. Pop. 29,042.

Essex, a county which forms the N. E. extremity of Vermont. Area, 790 square miles. It is bounded on the E. by the Connecticut River, and is partly drained by the Passumpsic. The surface is mountainous. It is intersected by the Grand Trunk and the Portland and Ogdensburg R. Rs. Capital, Guildhall. Pop. 6811.

Essex, a county in the E. of Virginia. Area, 300 square miles. It is bounded on the N. E. by the navigable Rappahannock River. The soil is sandy and moderately fertile. Grain and wool are produced. Capital, Tappahannock. Pop. 9927.

Essex, a post-village of Middlesex co., Conn., on the Connecticut River, 7 miles from its mouth, and about 17 miles W. of New London. It has one national bank, and manufactures of carriages and soap. Pop., including Essex township, 1669.

Essex, a township of Kankakee co., Ill. Pop. 990.

Essex, a township of Stark co., Ill. Pop. 1538.

Essex, a township of Porter co., Ind. Pop. 228.

Essex, a post-township of Essex co., Mass., on a branch of the Eastern R. R. It has ten shipyards. Essex-built vessels have a high reputation. Pop. 1614.

Essex, a post-township of Clinton co., Mich. Pop. 1501.

Essex, a post-township of Essex co., N. Y. romantically situated on Lake Champlain. It has manufactures of iron, lumber, lime, shipping, woollen goods, etc. Pop. 1600.

Essex, a post-township of Chittenden co., Vt., 8 miles E. of Burlington, at the junction of the Burlington division with the main line of the Vermont Central R. R. Essex has a classical institute, and manufactures of wall-paper, gloves, shirts, metallic wares, furniture, brick, and other goods. Pop. 2022.

Essex (Robert **Devereux**), second earl of, an English courtier, born in Herefordshire Nov. 10, 1567, was the eldest son of Walter, the first earl of Essex. He served with distinction at the battle of Zutphen in 1586, and became master of the horse in 1587. In 1588 he succeeded the earl of Leicester as the prime favorite of Queen Elizabeth. He had a handsome person, agreeable manners, and other popular qualities. He married, in 1590, Sir Philip Sidney's widow, who was a daughter of Sir Francis Walsingham. He commanded the land forces of the expedition which took Cadiz in 1596, and he became earl-marshal of England in 1597. He was appointed lord lieutenant of Ireland, and was sent in 1599 to subdue a revolt of the Irish, but was not successful. Having been removed from office in disgrace, he returned to London, and provoked the queen by his rash and disrespectful conduct. It is stated that he tried to excite an insurrection in London. He was tried for treason, and beheaded Feb. 25, 1601. He was brave and generous, but too vain and ambitious.

Essex (Thomas Cromwell), earl of. See Cromwell.

Ess'ling, a village of Austria, on the Danube, 7 miles E. of Vienna, was the scene of an indecisive battle between Napoleon and the Austrians in May, 1809. (See Aspern.)

Esslingen, a town of Würtemberg, on the river Neckar, 9 miles by rail E. S. E. of Stuttgart. It is on the railway which connects Stuttgart with Ulm, is enclosed by walls, and has an old castle. It has a splendid Gothic church, built in 1440, with a spire 230 feet high, a handsome town-hall, and a richly endowed hospital. Here are important manufactures of machinery, cotton and woollen stuffs, paper, silver-ware, and wine. Esslingen became in 1209 a free city of the German empire. Pop. in 1871, 17,941.

Established Church, a term applied to any church organization which is exclusively recognized by the government of a country, or which has peculiar privileges under any government. Most Mohammedan and heathen countries have an established religion, though in nearly all more or less freedom of opinion is allowed. Christianity first became the established religion of the Roman world under Constantine the Great. Charlemagne strengthened the Church establishment in the West; and throughout the Middle Ages the unity and authority of the Church exercised a great, and in some respects a very salutary, influence upon the crude society of those times. Some of the early Protestant Reformers advocated a separation of Church and State, but in every European country where Protestantism prevailed some one of its divisions became the State Church; and the same was the case in most of the English North American colonies. Whatever may have been the effect for good or evil in those times, it is not only the popular opinion, but the conclusion of the best thinkers of our time, that the day for church establishments has gone by, and that the voluntary system is on all accounts greatly to be preferred.

Estafette, ĕs'tȧ'fĕt', a French word which is used in nearly all the countries of Europe to signify an *express* employed to convey packages, letters, etc. Articles sent by the estafette are consigned to the care of successive postilions, who are changed with every relay of horses.

Estaing, d' (Charles Hector), Count, a French naval officer, born in Auvergne in 1729. He served in the land army in India, and was appointed lieutenant-general of the naval armies in 1763. He commanded as vice admiral a fleet sent in 1778 to fight for the U. S. His fleet was damaged by a storm near Newport in August of that year. He soon repaired his ships, and sailed to the West Indies, where he captured Grenada in 1779. In September of that year he attacked the British at Savannah without success. He returned to France in 1780, and was guillotined April 28, 1794.

Estaires, a town of France, department of Nord, on the Lys. It has considerable manufactures of linen, napkins, soap, candles, and oil. Pop. 7120.

Estate, a word sometimes used to indicate property generally, whether real or personal. Sometimes it includes land alone. In law it denotes the interest which one may have in property. It means the time during which ownership exists, as for a year, or for life, or for ever. Under the common law, estates in land are divided, as regards the *quantity* of interest, into two general divisions: 1st, freehold estates; 2d, estates less than freehold.

1st. A freehold is an estate which may last for life or longer. An estate which is circumscribed within a certain number of years, or one in which the possessor has no fixed right of enjoyment, is less than freehold; and although, in fact, it may endure longer than the life of its first possessor, still the law regards it as a lower estate than a freehold; it is in the eye of the law personal property, and does not descend to heirs, though it may pass to executors or administrators.

Freehold estates are divided into estates of inheritance, which pass to heirs, and estates not of inheritance; the former are again divided into estates in fee simple and estates in fee tail. A fee simple is the most extensive and highest interest a man can have in land. If not aliened or devised, it passes to heirs generally. A fee tail, on the other hand, is an estate which is limited to certain particular heirs or to a certain class of heirs, to the exclusion of the others, as to the heirs of one's body, which excludes collateral heirs, or to the heirs male of one's body, which excludes females. Fee tails have had only a limited existence in this country, and are now, in general, abolished. In New York, by the law of 1782, they were changed into estates in fee simple.

Freeholds not of inheritance are for life only, either for the life of the tenant or of some other person or persons, when the estate is called an estate *pur autre vie*. Life estates are created by the act of the parties or by operation of law. An example of the former is where A conveys land to B for the term of his natural life, or where A conveys land to B without expressing the duration of the term. Here, under the common law, B would take only a life estate, but by statute in New York and many other States a grant or devise of real estate passes all the interest of the grantor or testator, unless the intent to pass a less estate or interest appears in express terms or by necessary implication. Curtesy and dower are life estates created by act or operation of law. When a man marries a woman seized at any time during the coverture of an estate of inheritance, and has issue born alive during the life of the wife, which might possibly inherit from the mother, the husband on the death of the wife has an estate for his life in her land, which is termed curtesy. In many of the States a wife may alien or devise her land so as to defeat this estate, and in some it is altogether abolished. When a husband dies, the wife has a life estate in a third of all the land in which at any time during coverture he had an estate of inheritance. This estate of the wife is termed dower. In some of the States, by statute, a wife is entitled to dower only in the land of which her husband died seized, and in most of the States the interest which a wife takes in the land of her deceased husband has been a matter of statutory regulation.

2d. Estates less than freehold. These are divided into estates for years, at will, and by sufferance. An estate for years is an estate for a determinate period, whether it be for a longer number of years than a human life, or for only a portion of one year. An estate at will is where one man lets land to another to hold at his will, as well as that of the lessee. Such an estate is terminated by either party on due notice. Out of estates at will a class of estates has grown up called estates from year to year, which can be terminated only by six months' notice, expiring at the end of the year. An important element in creating this estate

is the payment of rent. An estate by sufferance arises when one comes into the possession of land by agreement, and holds over after his original estate has expired, and without any agreement, express or implied, by which it is continued. The landlord has a right to enter at any time, and dispossess the occupant without notice.

These estates may be created upon condition—that is, their existence may depend on the happening or not happening of some event whereby the estate may be created, enlarged, or defeated. A fee, a freehold, or a term for years may thus be upon condition. The condition must either be precedent—that is, must happen before the estate can vest or be enlarged—or subsequent, when it will defeat an estate already vested.

Estates may also be legal or equitable. They are called "equitable" when the formal ownership is in one person and the beneficial ownership is in another. Another form of expression is that a trust is created. This distinction does not affect the nature of the estate. Thus, a trust estate may be a life estate or a fee, and in the latter case is transmissible to heirs as though it were a strict legal estate.

In regard to the time of enjoyment, estates are divided into estates in possession and estates in expectancy. An estate in possession is one in which there is a present right of enjoyment. Estates in expectancy are those which give either a vested or contingent right of future enjoyment. They are subdivided into remainders, which are created by the express words of the parties, as where one gives a life estate in land to A, and the remainder to B; and reversions, which arise by operation of law, as where one gives an estate for life to A; here, on the death of A, the estate reverts to the grantor or his heirs, who, until the termination of A's estate, are said to have a reversion in the land. Besides these, there are future estates introduced into the law by the doctrine of uses (see USES) which are not governed by the technical rules applicable to remainders. They are called "springing and shifting uses." Similar provisions in a will are termed "executory devises."

In regard to the number of owners, estates are divided into estates in severalty, in joint tenancy, in common, and in coparcenary. An estate in severalty is one which has only a single owner. An estate in joint tenancy is an estate owned jointly by two or more persons, whose title is created by the same instrument. The distinguishing characteristic is the right of survivorship. On the death of any tenant his interest is extinguished, and the estate goes to the survivors. By the common law, where an estate is conveyed to two or more persons without indicating how it is to be held, it is understood to be in joint tenancy. But in most of the U. S. this rule has been changed by statute, and persons to whom an estate is conveyed or given take as tenants in common, unless they hold as trustees. An estate in common is where separate and distinct but undivided interests in land are held by two or more persons. Each tenant is considered as solely seized of his share, which on his death descends to his heirs. An estate in coparcenary is the estate which female heirs take in the land of an intestate ancestor. In this country this estate is essentially extinguished, and heirs take as tenants in common.

The English classification of estates in land has been much modified by statute in the U. S., but it forms the basis of the law of real estate throughout the American Union, except in Louisiana, where the civil law prevails.

T. W. DWIGHT.

Estates, The Three, or the **Estates of the Realm** [Fr. *Les États Généraux*], the political name designating the three classes of feudal society: 1, the nobles; 2, the clergy; and 3, the commons, including the bourgeois or middle class of towns and the peasantry. The term "estates of the realm" was used in Scotland before the Union (1707) as synonymous with Parliament. It consisted of lords spiritual (or mitred clergy), lords temporal (including the nobles and the commissioners of shires and stewartries), and the representatives, called burgesses or commissioners, of royal burghs. They met in one assembly, and usually voted in one body. The "States General" of France were rarely convened after the fourteenth century, and had little or no legislative power. One of the exciting causes of the French Revolution was the dispute which arose between the "third estate" (*tiers état*), or bourgeois, and the nobles and clergy, as to whether the third estate had a right to sit with the first and second. This dispute arose in 1789. In Sweden there were four estates—nobles, clergy, bourgeois (middle class), and peasants, each sitting in a separate house; but since 1865 there are but two legislative houses, both representative. A convention of the States General was long (1580–1795) the supreme power in the Dutch republic.

Es'te (anc. *Ates'te*), a town of Italy, in the province of Padua, is picturesquely situated on the slope of the Euganean Hills, 18 miles, by rail, S. S. W. of Padua. Here is a fine feudal castle called Rocca belonging to the noble family of Este; also an interesting Romanesque church with a leaning tower. Este has manufactures of silk goods, hats, and earthenware. Pop. 8697.

Es'te, an ancient sovereign family of Italy, from which the monarchs of Great Britain are descended. Among the first princes of this family was Oberto I., who married a daughter of Otho, king of Italy, and died about 927 A. D., leaving a son, Oberto II. The family received several districts and towns to be held as fiefs of the German empire. Albertazzo II., who succeeded Oberto II. about 1020, married a German princess of the house of Guelph or Welf. Their son, Guelph IV., received in 1071 the investiture of the duchy of Bavaria. He was the ancestor of the houses of Brunswick and Hanover. Obizzo took the title of marquis of Este in 1137, and Azzo VI., marquis of Este, was chosen as their sovereign by the people of Ferrara in 1208. Azzo VII. of Este was the chief of the Guelph faction in the civil war which they waged against the Ghibelines. He died after a long reign in 1264. His successor, Obizzo II., added to his dominions in 1288 the city of Módena, at the request of its citizens, who chose him as their sovereign. Died in 1293. Ercole (or Hercules) I., who began to reign in 1433, was noted as a patron of literary men. His son, Alfonzo I., duke of Ferrara and Módena, who reigned from 1505 to 1534, was an able statesman and general. He married the notorious Lucretia Borgia. He was succeeded by his son, Ercole II., who married Renée, the Protestant daughter of Louis XII. of France. Died in 1559. The next duke of Ferrara was Alfonzo II., a son of Ercole II. He was a patron of the poet Tasso, whom he afterwards imprisoned and treated with cruelty. He died without issue in 1597, when his cousin Cesare became duke of Módena, but lost Ferrara, which was annexed to the Papal States. The dukes who reigned after the death of Alfonzo II. were comparatively obscure and feeble. Alfonzo IV., who became duke of Módena in 1658, had a daughter Mary, who was the second wife of James II. of England, and a son, Francis II., who died without issue in 1694. The title was then inherited by Rinaldo, who, by his marriage with a daughter of the duke of Brunswick-Luneburg, united the Italian and German branches of the family. He died in 1737, and was succeeded by his son, Francis III., who died in 1780. Maria Beatrice, a granddaughter of Francis III., was married to Ferdinand, archduke of Austria. They had a son, Francis, who became duke of Módena in 1814, and died in 1846, leaving a son, Francis V., who was the last duke of Módena. He was deposed in 1859 by his revolted subjects joining the general movement for Italian unity. (See POMPEO LITTA, "Famiglia Celebri Italiane.")

Estella [Sp. pron. ês-têl'yâ], a city of Spain, in the province of Navarre, 22 miles S. W. of Pampeluna. It is well built, and has a fine church with a lofty tower, a college, and a hospital; also manufactures of linen and woollen fabrics, brandy, and earthenware. Pop. 5593.

Este'pa (anc. *Astapa*), a town of Spain, in the province of Seville, 60 miles E. S. E. of Seville. It has a church which is a noble specimen of Gothic architecture, and a fine palace; also manufactures of baize, oil, etc. Marble is quarried in the vicinity. Pop. 8133.

Estepo'na, a town of Spain, in the province of Malaga, on the Mediterranean, 63 miles E. of Cadiz. It has an old Roman castle, is well built, and has extensive sardine-fisheries. Pop. 9316.

Es'terhazy, an ancient and noble family of Hungary, which has produced many eminent men and which owns large estates.

Esterhazy (NICHOLAS JOSEPH), a grandson of Paul, was born Dec. 18, 1714. He became a privy councillor and field-marshal-general. He was a liberal patron of musicians. Died Sept. 20, 1790.

Esterhazy de Galantha (NICHOLAS), PRINCE, a son of the preceding, was born Dec. 12, 1765. He was distinguished as a diplomatist, and obtained the military rank of field-marshal. He was employed as ambassador to Paris, London, and St. Petersburg between 1801 and 1816. He owned an immense fortune, and founded a rich collection of paintings in Vienna. Died Nov. 25, 1833.

Esterhazy de Galantha (PAUL), PRINCE, was born Sept. 8, 1635. He became a field-marshal in the Austrian army before the age of thirty, and was chosen palatine of Hungary in 1681. In 1686 he took Buda from the Turks, and in 1687 was created a prince of the empire. Died Mar. 26, 1713.

Esterhazy de Galantha (PAUL ANTONY), PRINCE, born Mar. 10, 1786, was a son of Nicholas, noticed above. He was ambassador from Austria to London in 1815–18, and again in 1830–38. In Mar., 1848, he became minister of foreign affairs in the liberal ministry of Hungary,

but he prudently resigned about the time when the war broke out, and he took no part in the war. He owned more land than any subject of the Austrian empire, and had a fine palace at Eisenstadt. Died May 21, 1866.

Es'ther [which means "star"], the Persian name of **Hadas'sah** [which means "myrtle"], a beautiful Jewish maiden, who became the queen of Xerxes, king of Persia (B. C. 486–465). Some critics make her a niece, others a cousin, of Mordecai the Benjamite, who became prime minister of Persia in place of Haman the Amalekite. She is certainly not to be identified with Amestris, the "Persian Jezebel." Her connection with Xerxes was subsequent to his disastrous invasion of Greece.

Esther, Book of, one of the latest of the canonical books of the Old Testament, consisting of ten chapters, and relating events which gave rise to the Jewish feast of Purim. The Jews call it emphatically *Megillah*, "the Roll." The whole of it is read in Jewish synagogues every year at the feast whose origin it explains; and still, in many synagogues, with noisy demonstrations, such as hissing, and clapping of hands, and stamping of feet at the mention of Haman's name. The inspiration of the book and its right to a place in the canon have been sharply questioned. Much account is made of the singular fact that the name of God does not once occur; that, although fasting is spoken of, no mention is made of prayer; and that the religious tone of the book throughout is low. On the other side it is urged that the providence of God is magnified; that we have a vivid picture of manners and morals at the Persian court; and, above all, a most valuable exemplification of the unspiritual character of that portion of the Hebrew people who chose not to return to the Holy Land. The book appears to have been written in Persia soon after the occurrence of the events related in it, but by whom critics are not agreed. Its authorship cannot be determined.

Esther, Apocryphal Book of, consists of the ten canonical chapters described above, with interpolations here and there, and the addition of six chapters at the end. These additions are found in the Septuagint, and in versions made from it, but not in the Hebrew. For this reason Jerome placed them together at the end of Esther, but Luther was the first to place them in the Apocrypha. The object of the unknown author was to give a more religious tone to the book of Esther than it originally possessed. Though considered spurious by all Protestant churches, the Greek, Armenian, and Roman Catholic churches accept these additions as canonical.

Es'therville, a post-village, capital of Emmett co., Ia., is a rapidly growing town, pleasantly situated on the E. branch of the Des Moines River. It has a school-house costing $8000, and superior educational advantages, a bank, newspaper, machine-shop, two hotels, two saw and grist mills, two churches, etc. Principal business, farming and stock-raising. Pop. of village, 168; of township, 480.

DAY & JENKINS, Eds. "VINDICATOR."

Estho'nia, or Reval [Ger. *Esthland*], a government of Russia, and one of the Baltic provinces, is bounded on the N. by the Gulf of Finland, on the E. by St. Petersburg, on the S. by Livonia, and on the W. by the Baltic Sea. Area, 7610 square miles. The surface is generally flat, and extensively covered with forests of pine; the soil is sandy, and in some parts marshy. The staple products are grain, hemp, flax, tobacco, and cattle. The population of the towns and the nobility are predominantly German, while the people of the rural districts are mostly Esthonians, who belong to the Finnish race. Ninety-six per cent. of the population belongs to the Lutheran Church. The language of the Esthonians is soft and melodious. Their literature consists chiefly of poems, the most important of which is the epic poem "Kalexa Poig." The Esthonian tribe inhabits also a part of Livonia, and embraces an aggregate population of about 600,000. Esthonia was conquered from the Swedes by Peter the Great in 1710. Capital, Reval. Pop. in 1867, 322,668.

Es'till, a county in E. Central Kentucky. Area, 300 square miles. It is intersected by Kentucky River. The surface is hilly; the soil fertile. Coal and iron are found. Grain and tobacco are produced. Capital, Irvine. Pop. 9198.

Es'tillville, a post-village, capital of Scott co., Va., about 350 miles W. by S. from Richmond. Pop. of Estillville township, 2400.

Estop'pel, a principle of law, whereby one is bound by his previous admission or declaration—not on the ground that it is true, but because to dispute it is regarded as contrary to sound policy or as subversive of the ends of justice. Estoppels are: of record, of deed, and *in pais*.

1. *Estoppel of Record.*—By record is here meant the record of a tribunal of a judicial character. No one is permitted in a legal proceeding to contradict an admission made by him in his pleading. So the judgment of a court of competent jurisdiction is in most instances absolutely unimpeachable. If the judgment is *in rem*, that is, if it determines the status of a person or thing it is binding on all persons, whether rendered by a domestic or a foreign tribunal. If the judgment is *in personam*, it is conclusive if rendered by a domestic court, and the better opinion is that the same rule applies to a foreign judgment, unless it be shown in either case that the court which pronounced it did not acquire jurisdiction, or that the judgment was obtained by fraud. This respect for the decisions of foreign tribunals is based on the comity which nations show each other, and on the necessities of commerce. The Constitution of the U. S. provides that full faith and credit shall be given in each State to the public acts, records, and judicial proceedings of every other State. Under this provision the judgments of the courts in one State are binding on the tribunals of another State, without reference to the doctrine of the comity of nations. But a judgment *in personam* has no binding force except as to the parties to the action in which it is rendered, and those who claim under them, who are technically said to be in privity with them. The doctrine of estoppel by record does not prevent one injured by a judgment from taking direct proceedings to attack it, and judgments are often set aside on application to the court in which they are rendered. In certain cases courts of equity interfere by injunction to stay proceedings on judgments obtained in courts of law.

2. *Estoppel by Deed.*—A party to an instrument under seal is bound by the statements contained in it to those who have acted upon such statements, or, as Lord Mansfield puts it, no man is allowed to dispute his own solemn deed. The estoppel applies to recitals as well as to direct averments. To create an estoppel the recital must be clear and of a material fact, and consistent with the general scope of the deed. As a general rule, estoppels of this class are reciprocal. Thus, in the case of a lease, while the tenant cannot dispute the title of the landlord, the latter cannot deny the right of the tenant. There is also an estoppel by deed of a more technical nature. This grows out of a covenant of warranty. Thus, should a person having no title to land convey with covenant of warranty, and afterwards acquire the title, he would be estopped by his covenant from asserting his claim to the land. The object of this rule is to avoid "circuity of action."

3. *Estoppel in Pais.*—In the time of Lord Coke this division of the principle was applied only to certain acts relative to the title of real estate which the law regarded as possessing equal solemnity and notoriety with a deed. Since then the principle has been greatly extended, and now presents a twofold aspect. In the first place, it is rigorously applied, from motives of general policy, to certain classes of cases. A bailee in general cannot dispute the title of his bailor, neither is the endorser or acceptor of negotiable paper allowed to deny the genuineness of any of the preceding names to the paper. In the second place, it is applied when good conscience requires that one should not be allowed to insist on his strict legal rights. The rule which governs its application here may be thus stated: Where one has made a representation or an admission by his words, his action, or, in cases where it is his duty to speak, by his silence, with the intent or expectation, or reasonable grounds for expectation, that others should rely and act thereon, he shall not be permitted to prove that the representation or admission was untrue, if thereby injury would result to one who has in good faith acted upon it. It was at one time supposed that *fraud* was an essential element to constitute an estoppel *in pais*. The better opinion is that no fraudulent design is necessary. It is enough if the party claiming the benefit of the estoppel has acted upon the representations as before stated. The principle, thus limited and applied, is free from the technicalities and harshness which for a long time caused the doctrine of estoppel to be regarded with suspicion by the courts; it is constantly invoked for the prevention of fraud and injustice, and has become one of the most effective agencies of the law. A few instances of its practical application may be cited: A principal may by his conduct be estopped to deny that a certain person is his agent; one who has permitted himself to be held out as a member of a mercantile firm may be estopped as to creditors from denying his membership; a man who has held out a woman as his wife may be estopped from proving that she is not as to tradesmen who have in good faith supplied her with the necessaries of life on his credit. The principle has been extended to the law of real estate. An owner of land who has induced another to incur heavy expenditure on the representation that the latter was owner would be estopped from asserting his own title.

T. W. DWIGHT.

Esto'vers, the right of a tenant to take wood from the

demised premises for fuel, fences, and general agricultural purposes. This right may be claimed by any tenant, whether for life, for years, or at will, unless forbidden in his lease. But only a reasonable amount of wood can be taken; the tenant must not destroy the timber, nor do any permanent injury to the inheritance.

Estrades, d' (GODEFROI), COMTE, a marshal of France and able diplomatist, born at Agen in 1607. He negotiated the cession of Dunkirk to France in 1662, and rendered important military services in Holland between 1672 and 1675. He represented France at the congress of Nymwegen, 1078. Died Feb. 26, 1686.

Estray' [remotely from the Lat. *extra*, "outside," and *vagor, vagari*, to "wander"], in law, is a domestic animal (the owner of which is unknown) found wandering outside the pasture or other enclosure where it belongs. In England the owner has a year and a day to claim such cattle in, and the proprietor of the enclosure where they are found must make due proclamation in a church and in two market-towns. When these conditions are fulfilled, they belong to the proprietor of the enclosure where they are found. The law of estrays varies in the different States of the Union. In some, after the estray has been duly advertised and kept a certain length of time, it is sold to pay the charges for advertising and keeping, any balance going to the town treasury. Cattle running about contrary to local, municipal, or other regulations, or breaking into growing crops and doing damage to them or to other property, can in most places be sent to a public pound, and after a short time sold to pay damages and expenses.

Estrées, d' (GABRIELLE), a beautiful Frenchwoman, born in 1571, was a sister of the first duke of Estrées. She was the mistress of Henry IV., who gave her the title of duchess. It is said that he intended to marry her, but he was prevented by her early death (April 10, 1599). She was amiable and graceful. Her brother, the duc d'Estrées, was a marshal of France, and had a son who was also a marshal.

Estremadu'ra, a province of Portugal, is bounded on the N. by Beira, on the E. and S. by Alemtejo, and on the W. by the Atlantic, and intersected by the river Tagus. Area, 6873 square miles. The surface is mostly hilly; the soil is partly fertile and partly sterile. It is subject to frequent earthquakes. Among the minerals are granite, marble, and coal. The staple productions are wine, oil, cork, fruits, and grain. Pop. in 1868, 837,451. Capital, Lisbon.

Estremadu'ra, a former province of Spain, was bounded on the N. by Leon, on the E. by New Castile, on the S. by Andalusia, and on the W. by Portugal, and intersected by the rivers Tagus and Guadiana. Between these rivers a long chain of mountains extends nearly E. and W. The northern and southern parts are also mountainous. The soil is fertile, but not cultivated to much extent. Large flocks of sheep are pastured on it. This province contains mines of copper, lead, silver, and coal, which are neglected. It is comprised in the present provinces of Badajos and Cacéres. Pop. in 1867, 733,749.

Estremoz', a fortified town of Portugal, in Alemtejo, is about 23 miles N. E. of Evora and 82 miles E. of Lisbon. It has a strong castle on a hill, around the base of which the town is built. Here are famous manufactures of porous jars which have the property of keeping water cool. The forms of these jars are said to be classical. Pop. in 1863, 7274.

Es'tuary, or **Æs'tuary** [Lat. *æstua'rium*, from *æs'tus*, the "tide," because the tide is apt to be felt even more in an estuary than in the open sea], in geography, a term applied to the wide mouth of a river where the tide meets the current; also an arm of the sea or a frith.

Esz'ek, Es'sek, or **Esseck** (anc. *Mur'sia* or *Mur'sa*), a strongly fortified town of the Austro-Hungarian monarchy, the capital of Slavonia, is on the river Drave, 13 miles from its entrance into the Danube, and 150 miles S. by W. from Pesth. It has a prosperous trade, facilitated by the steam navigation of the river. It contains an arsenal, a townhouse, and a normal school. Pop. in 1869, 17,247.

Étampes, formerly **Estampes** (anc. *Stam'pæ*), a town of France, in the department of Seine-et-Oise, is on the Paris and Orléans Railway, 31 miles by rail S. S. W. of Paris. It has an old Gothic church, a castle, and many flouring mills; also manufactures of hosiery, linen thread, counterpanes, and soap. Pop. in 1866, 8288.

Étampes, or **Estampes** (ANNE), DUCHESS OF, a French lady, born in 1508. She was a favorite mistress of Francis I., and exerted much influence over public affairs. She is said to have been a woman of superior talents. Died in 1576.

Et'anin [Arab.], the fixed star called γ Draconis. Observations made on this star by James Bradley led him in 1727 to the discovery of the aberration of the fixed stars.

Eta'wah, a decayed town of India, in the N. W. Provinces, is on the Jumna, about 70 miles below Agra, and on the East Indian Railway, 97 miles N. W. of Cawnpore, and 837 miles from Calcutta. It presents some remains of former grandeur. Pop. about 20,000.

Etching. See ENGRAVING, by PRES. M. B. ANDERSON, LL.D.

Ete'ocles [Gr. Ἐτεοκλῆς], a mythical king of Thebes (in Bœotia) and a son of Œdipus. He and his brother Polynices agreed to reign alternately over Thebes, but Eteocles usurped the throne when his brother's turn came to reign. The famous expedition of the Seven against Thebes was undertaken to restore Polynices, who killed Eteocles in single combat.

Ete'sian Winds [Gr. ἐτησίαι, or ἐτησίαι ἄνεμοι; *i. e.* "annual (or periodical) winds," from ἔτος, a "year"], northerly and north-easterly winds which prevail in summer throughout a great part of Europe and in Northern Africa. The name occurs in its Greek form in several ancient writers, and is now occasionally seen in meteorological works. These winds arise in a great degree from the heat of the African Sahara.

Étex (ANTOINE), a sculptor, painter, engraver, architect, and author, was born at Paris Mar. 20, 1806, was educated at Paris and Rome, and has achieved distinction in all the departments to which he has given attention. He has published an "Essai sur le Beau" (1851), "Cours Élémentaire de Dessin" (1859), and "J. Pradier, Ary Scheffer: Études" (1859).

Ethal. See SPERMACETI, by PROF. B. SILLIMAN, M. D.

Eth'elbert, king of Kent, ascended the throne about 560 A. D. He became the head or most powerful prince (bretwalda) of the Heptarchy about 590. His wife Bertha, a daughter of the king of Paris, was a Christian, and induced Ethelbert and his subjects to profess Christianity in 597 A. D. Saint Augustine was instrumental in their conversion. Ethelbert gave to the Anglo-Saxons their first written code of laws. Died in 616 A. D.

Ethelbert, Anglo-Saxon king of England, was a son of Ethelwolf. He began to reign over Kent, Essex, and Sussex in 852 A. D., and obtained also the throne of Wessex on the death of his brother Ethelbald in 860. He died in 865 A. D.

Eth'elred (or **Æthelred**) **I.,** Anglo-Saxon king of England, succeeded his brother Ethelbert in 866 A. D. In the first year of his reign the island was invaded by Danes, who conquered a large part of his kingdom. His brother Alfred defeated the Danes in 870. Ethelred was killed in battle at Merton in 871 A. D., and was succeeded by Alfred the Great.

Ethelred II., surnamed THE UNREADY, Anglo-Saxon king of England, a son of Edgar, was born in 968 A. D. His mother was Elfrida, notorious for her crimes. He succeeded his half-brother, Edward the Martyr, in 978. In his disastrous and inglorious reign the kingdom was invaded and ravaged by the Danes, to whom he paid large sums of money to purchase peace, but they soon renewed their piratical incursions. The Danish king Sweyn took London in 1014, and Ethelred fled to the court of the duke of Normandy, who was his wife's brother. He died in 1016, leaving two sons—Edmund Ironside and Edward the Confessor.

Eth'elwolf, Anglo-Saxon king of England, was the eldest son of Egbert, whom he succeeded in 836 A. D. His kingdom was harassed by several incursions of the Danes, who pillaged London in 851. He defeated these invaders at Okely in that year. He married, in 856, Judith, a daughter of Charles the Bald, king of France. Died in 858 A. D. He left four sons—Ethelbald, Ethelbert, Ethelred, and Alfred the Great.

Ethene. See ETHYLENE.

E'ther [Gr. αἰθήρ; Lat. *æ'ther*, originally applied to the purer upper air; hence any subtile fluid], in organic chemistry, is a name given to numerous compounds, which are usually very volatile, fragrant, and, with a few exceptions, highly inflammable; they are generally derived from alcohols by the action of acids. When the alcohols are simply dehydrated by the action of the acid, "simple ethers" are produced, which are oxides of the alcohol radicals analogous to metallic oxides. Thus,

Common Alcohol. Common Ether. Water.

$$2C_2H_5.H.O = (C_2H_5)_2O + H_2O.$$

When the acids combine with the alcohol radical, "compound ethers" are produced, analogous to metallic salts. Thus,

Common Alcohol. Acetic Acid. Ethyl Acetate. Water.

$$C_2H_5.H.O + H.C_2H_3O_2 = C_2H_5.C_2H_3O_2 + H_2O.$$

"Haloid ethers" are compounds of the alcohol radicals with the halogens, chlorine, bromine, iodine, etc. They

are analogous to common salt (NaCl). Amyl chloride ($C_5H_{11}Cl$) and methyl iodide (CH_3I) are examples.

Sulphur, selenium, etc. form compounds analogous to the simple or oxygen ethers.

Common ether, properly known as ethylic ether, commonly and very incorrectly called sulphuric ether ($(C_2H_5)_2O$, is generally regarded as an oxygen ether, and in this view is sometimes called ethyl oxide. It is formed by the action of sulphuric acid or some other dehydrating agent upon strong ethylic (common) alcohol. Ethylic ether is a fragrant, colorless, transparent, and highly mobile liquid, with a specific gravity of .720, and a boiling-point of 96° Fahrenheit. It is extremely combustible, and so volatile that when applied to the hand it causes a profound sensation of cold. Though very light in the liquid state, its vapor is more than twice as heavy as air. It is very useful in the chemical laboratory, especially as a solvent of fats and oils.

Ether is much used in medicine and surgery, both as a diffusible stimulant and as an anæsthetic. It was probably the first complete anæsthetic ever employed. It was introduced by Dr. Morton of Boston, Mass. (See ANÆSTHETICS.)

The other more important ethers are "acetic ether" (ethyl acetate, $C_2H_5.C_2H_3O_2$), an exceedingly fragrant stimulant and antispasmodic; "butyric ether" (ethyl butyrate, $C_2H_5.C_4H_7O_2$), used in preparing artificial pineapple syrup; "pelargonic ether" (ethyl pelargonate), for making artificial quince flavor; "amyl acetate," for making "jargonelle pear essence," extensively used in confections, besides an immense number of other ethers and mixtures used in artificial flavoring; "iodic ether" (ethyl iodide), used in medicine; "nitrous ether" (ethyl nitrite, $C_2H_5.NO_2$), used in making "sweet spirits of nitre."

Ether, a hypothetical medium which is assumed to pervade all space, and which is regarded as possessing extreme tenuity and elasticity, and as being the medium of the transmission of light and heat, these forces being transmitted by vibrations or undulations of this ether.

Eth'erege, or Etheridge (Sir GEORGE), an English dramatist, born in 1636. He wrote "Love in a Tub," "Sir Fopling Flutter, or the Man of Mode," and other successful comedies. He was a wit and libertine. Died about 1692.

Ethics. See MORAL PHILOSOPHY, by PRES. NOAH PORTER, S. T. D., LL.D.

Ethio'pia [Lat. *Æthiopia;* Gr. *Αἰθιοπία*, from *αἴθω*, to "burn," and *ὤψ*, "face;" Heb. *Cush*], a name given by ancient geographers to the regions situated S. of Egypt and Libya. The name Ethiopians was originally applied by the Greeks to all the peoples who lived in the southern parts of the known world, including the dark-colored natives of India. As the ancient Greeks and Romans had but little intercourse with the Ethiopians, the accounts which they have transmitted to us are very defective and uncertain. They supposed Ethiopia to be inhabited by several races called Troglodytes, Pygmies, Macrobii, and Blemmyes. According to some traditions, the Egyptians derived their civilization or came themselves from Ethiopia. The connection between Egypt and Ethiopia was at all periods intimate, but it is now generally believed that civilization ascended the Nile, instead of descending it. In its extended sense, Ethiopia corresponded to the modern Nubia, Sennaar, Kordofan, and Northern Abyssinia. The population of this vague region was a mixture of Arabian and Libyan races with the genuine Ethiopians. The latter had well-formed limbs, and a facial outline resembling the Caucasian in all but its inclination to prominent lips and a somewhat sloping forehead. Their language was Semitic. The Nubians and Shangallas of the present time are probably their descendants.

The term Ethiopia Proper was restricted to the kingdom of Meroë. The high civilization of Ethiopia, as attested by historians and confirmed by monuments, was confined to the island of Meroë and *Æthiopia Ægypti*. The kingdom of Meroë was bounded on the E. by the river Astaboras (Atbara) and on the W. by the desert of Bahiouda. It probably extended southward to the junction of the Blue Nile with the White Nile. The capital of this kingdom was Napata, on the Nile. It became one of the most powerful and civilized nations of the world as early as 1000 B. C. The government was a sacerdotal monarchy, the priests being the ruling class, as in Egypt. The military power of the Ethiopians was celebrated by Isaiah (xx. 5) and other Hebrew prophets, and the sacred history records their invasion of Palestine. In the eighth century B. C. an Ethiopian dynasty (the twenty-fifth of Egypt) reigned in Lower Egypt. The first king of this dynasty was Sabaco, whose son and successor, Sebichus (the So or Seva of the Bible), was an ally of Hoshea, king of Israel, in 722 B. C. It is stated that in the reign of the Egyptian king Psammetichus (630 B. C.) the military caste, numbering 240,000, migrated into Ethiopia. It was invaded by the army of Cambyses, king of Persia, in 530 B. C. According to Josephus, he conquered Meroë. In the reign of Augustus Cæsar, Candace, queen of Ethiopia, waged war against the Romans. Having been defeated, she sued for peace and became tributary to him in 22 B. C., but the Roman tenure of Ethiopia was always precarious. Early in the fourth century many Christian churches were planted in Ethiopia. (See ABYSSINIA, by PROF. A. J. SCHERM.)

Ethiopic Language and Literature. The name "Ethiopic language" is at present generally applied to the old written language of the Abyssinian Church. The name "Chaldæan language," which was given to it at the time when the knowledge of it was first introduced into Europe by J. Potken (1513), was incorrect. But even the name "Ethiopic language," by which it has been known since the middle of the sixteenth century, does not seem to fit exactly, for it has nothing in common with the language of that race called by the ancients Æthiopes (the Cushites of the Bible); and in the large empire of Abyssinia, which was called in the Middle Ages Ethiopia, there were and still are many other languages, some of which are related to, while others are of entirely different stock from, the Ethiopian. The native name is the Geez language. Geez, or, in the plural, *Ag'âzi* (*i. e.* "those who have travelled," or "the free"), was the name which the race who once spoke this language applied to itself, and consequently to its language; and modern philologists have begun to use "Geez" as the more accurate, in preference to "Ethiopic" language, the more general term. The Geez were one of the Semitic tribes, who had emigrated from Arabia to Abyssinia, and had settled in Tigre and its capital, Axoom. In the large Abyssinian empire which grew up around Axoom, and which was gradually Christianized after the fourth century, this Geez language became the official and the church language, beside which the dialects and languages of the different native tribes still continued to exist, but were not used as written languages. In this ruling position as the official language of the empire it continued to maintain itself until the middle of the thirteenth century, when, in consequence of a change of dynasties, the Amharic language gradually gained the ascendency at the imperial court, and entirely superseded the Ethiopic as the official language. But its position as the language of the Church and of the scholars of Christian Abyssinia it did not lose in consequence of this political revolution. The clergy and literary men were for centuries compelled to have a knowledge of it, and understood it even well enough to write books; and even at the present day the old Geez books continue to be copied. During the last three hundred years books of all kinds have been prepared in the Amharic language, which is more familiar to the people, and even the Bible or parts of it have been translated, especially at the instance of the Protestant missionaries, into the modern languages of Abyssinia, in particular into the Amharic and Tigre, without diminishing, however, the influence of the old Geez translations. As a popular language the Geez has died out even in Tigre, its original home, or rather it has been modified in the mouths of the people into dialects. Among these descendants of the Geez language two principal dialects are distinguished: the Tigre, which is closely allied to the Geez, and which is spoken by nomadic tribes in the extreme north, in the regions bordering on Nubia and Sennaar, which for a long time have been cut loose from Abyssinia; and the Tigriña, which is spoken in the old province of Tigre and the neighboring districts, and which has degenerated more than the other in sounds, forms, and fulness of words, and is largely mixed with Amharic words. (A grammar of this language has recently been published by Prætorius, "Grammatik der Tigriñasprache," 1872.)

The Geez is a purely Semitic language, but still, in its way, is very peculiar, and is justly regarded as a special branch of the Semitic family. Its relation to the language of the Himyaritic monuments can hardly be said to be nearer than its relation to the Arabic as now written. It has, however, much in common with the entire Arabic group of languages, not only in regard to the stock of words, but also in regard to the system of sounds and the formation of words; and although it has never attained the fulness of forms of the Arabic, it has developed some Semitic peculiarities, even more consistently than the written Arabic. But in many words, roots, forms, and even in many syntactic forms, it agrees more with the northern Semitic languages, especially with the Hebrew, but also with the Aramaic and the Assyrian. It must therefore be assumed that the Geez, after its branching off from the northern Semitic, continued to develop itself in connection with the southern Semitic (Arabic) languages, but separated itself very early from these, and continued to go along its own path. For this reason it has still many peculiarities of the ancient Semitic languages—peculiarities which have been aban-

doned even in the Arabic; and in some respects has retained the most ancient forms (*e. g.* it has no article). Other forms it has developed in a peculiar manner, contrary to the method of all other Semitic languages (*e. g.* most of the prepositions and conjunctions). Especially in the method of construction it has formations which are hardly to be found in the other Semitic languages, and has acquired a flexibility of syntax which distinguishes it favorably from all the other languages related to it. On the other hand, besides many ancient and peculiar forms in the Geez, we meet, strange to say, with many forms which the other Semitic languages only reached in their latest stages of development (*e. g.* the disappearance of the inner passive and of the participial form, the dropping of short vowels, etc.); and we may infer from this that the Geez, as it is presented to us in the Abyssinian books, has already passed through a long stage of development. From this it is seen that the study of the Geez is very important and instructive to the Semitic philologist.

The Geez has never been grammatically treated by native (Abyssinian) scholars. In Europe, after several very incomplete attempts in the sixteenth and seventeenth centuries, it was treated of in a grammatical and lexicographical exposition, which for its time was excellent, by Hiob Ludolf ("Grammar and Lexicon," 1661; 2d ed., Lexicon, 1699, Grammar, 1702). In accordance with the demand of modern linguistics, and on the basis of a much fuller knowledge of Ethiopic literature, the language has recently been treated of by A. Dillmann ("Grammar," 1857; "Lexikon," 1865).

The Geez is written with peculiar characters, which originally were identical with the Himyaritic and old Arabic characters found in the inscriptions of Syria and Assyria, and were afterwards only slightly modified. It is written not from right to left, but from left to right, and is also remarkable in that it separates the single words by two dots (:), and that the writing of vowels by means of little lines and hooks, which are attached to the consonants, is uniformly carried out. These characters were subsequently used in Abyssinia for the other dialects and languages also, especially for the Amharic and the Tigriña, but enriched by several new characters, so that they can be said to have become the universal alphabet of Abyssinia.

The oldest monuments of the Ethiopic characters and language which are known at present do not date beyond the first centuries of our era. They are coins and inscriptions; among the latter especially the large inscriptions of Axoom, which have been made known to the world by Rüppel in the account of his travels. They mostly show an archaic mode of writing the consonants, and the vowel-signs are only in their infancy. An Ethiopic literature began to exist since the introduction of Christianity into Abyssinia (in the fourth century), and has always retained a predominantly religious character. Its basis was the translation of the Bible, both the Old and New Testament, together with the semi-biblical, apocryphal, and pseudepigraphic books belonging thereto, which in the other churches were rejected or lost (as the book of Jubilees, of Enoch, the Apocalypse of Ezra, the Ascension of Isaiah, the Shepherd of Hermas, and others). The entire translation has been made from the Greek, but was afterwards revised several times—the Old Testament at last even from the Hebrew; and we must therefore distinguish between the old, middle, and latest revisions of the text. The pseudepigraphic books are nearly all printed. A critical edition of the Old Testament has been begun by Prof. Dillmann, but has only progressed to the second book of Kings. The Psalms and Solomon's Song have been published already several times. The New Testament was printed at Rome in 1548, and was reproduced in the London Polyglot with many mistakes. The edition (now out of print) of the English Bible Society (by P. Platt, 1826) gives a mixed text, which cannot be used for critical purposes. The other literature consists, for a large part, of translations of Greek and even Coptic works, and after Mohammedanism had taken root in Egypt, the mother-country of the Abyssinian Church, Arabic works also were translated. The literature comprises theological and religious works of every kind, such as collections of old canons (Clementina, Didascalia, Synodus), catenæ, and homilies, exegetical and dogmatic writings (especially those of Cyril, Epiphanius, Chrysostom, and also of the Syrian Fathers, especially those of the Monophysitic Church); Haimânôta Aban (*i. e.* a large collection of confessions of faith of the monophysitic teachers); lectionaries for the whole year, especially for the fasts and the Passion-time; horologia, liturgies of the mass, and church-books for the other sacraments, and for burials, church discipline (Faus Manfasawi), and church law (Fetha Nagast), Acta Sanctorum (Synaxa), a large number of monastic rules and monastic writings; in sacred and profane history and chronology the works of Joseph Ben Gorion, George Ben Amid, Abuschaker, and others, and even something relating to philosophy and the natural sciences.

Among the native productions of the Abyssinians themselves are dogmatic treatises, pseudonymous apocalyptical writings, numerous prayer-books and formulas, meditations, eulogies and biographies of saints, martyrs, monks, and archangels in prose and verse, mostly productions of monkish imagination and an insane belief in miracles. More important in their way are the large ancient hymn-books (Degnâ, Marâs'et, Me'raf), with hymns and antiphonies, not only for Sundays and holidays, but also for every day in the year, and containing formulas for the ceremonies in honor of all the saints of the calendar, with peculiar notes for singing, the use of which has been very imperfectly explained up to the present time. Most of these works, which indicate a considerable progress in religious poetry and music, have been traced back to a certain Jared in the sixth century. Besides these there were also large works on native history, and explicit annals of the several kings (from which J. Bruce in the second volume of his travels has given extracts), which were written in a peculiar language, a mixture of the Geez and the Amharic. After the extinction of the Geez a beginning of grammatical and lexicographical works was made, and was deposited in many Ethiopic-Amharic glossaries (Savasev). Much was also written in this period on medicine, witchcraft, exorcism, and divination for the superstitious people, either in Ethiopic-Amharic or entirely in the Amharic language. The poetry was almost entirely in the service of the Church and of religion. At all events, poems on secular affairs in the Geez language have not come down to us. Besides the peculiarly arranged hymns, only lyrical poetry was developed. The poems are divided into strophes of equal length. The construction of the strophes shows many varieties: the lines are rhymed; the syllables are neither measured nor counted. Of real poetic genius there are but few traces in these poems; many have of poetry nothing but the rhyme.

Of the entire literature very little has been printed besides the Bible. But it is at present very fully represented in manuscripts in all the large libraries of Europe, especially in Rome, Paris, Oxford, London, Tübingen, Frankfort-on-the Main, Vienna, and Berlin. The largest collection of manuscripts until lately was in the possession of Antoine d'Abbadie in France. But since the Abyssinian war the collection of the British Museum has been so largely increased that it is without doubt the largest in Europe. All the older and most of the later manuscripts are written on beautiful parchment. Among the manuscripts brought to Europe within the last century none date farther back than the fifteenth century.

AUGUST DILLMANN.
of the University of Berlin, Germany.

E'thiops Min'eral, the black powder obtained by triturating mercury with sulphur. It is a sulphide of mercury. The term Ethiops was formerly applied to other black powders.

Eth'moid [from the Gr. ἠθμός, a "sieve," and εἶδος, "form"] **Bone,** a spongy, irregularly cubical bone, situated below the anterior part of the brain, between the orbits of the eyes and at the roots of the nose. In man it consists of four parts—the cribriform plate, the perpendicular plate, and the two lateral masses. It is developed from three centres, commencing about the fifth month of fœtal life, and is completed about the sixth year of childhood. It appears to be formed of the united neurapophyses of the first cephalic vertebra.

Ethnology. See MAN AND HIS MIGRATIONS. By PRES. M. B. ANDERSON, LL.D.

E'thyl, or **E'thule** [from the Gr. αἰθήρ and ὑλή, "substance;" literally, a "substance of ether"], a name given to the organic radical (C_2H_5) contained in ether and alcohol. It may be obtained by the action of zinc on ethyl iodide. It is at ordinary temperatures a colorless and invisible gas, possessing a slight ethereal odor, and burning with a brilliant white flame. It is insoluble in water, but soluble in alcohol. It may be condensed to a liquid by the pressure of two and one-fourth atmospheres.

Ethyl'amin, a compound ammonia in which one atom of the hydrogen of the NH_3 is replaced by ethyl, C_2H_5. Thus,

Ammonia.		Ethylamin.
N {	H,	N { C_2H_5,
	H,	H,
	H.	H.

It is a mobile liquid, with a boiling-point of only 66° Fahrenheit, and a specific gravity of 0.6964. It has the odor and many of the reactions of ammonia, being a powerful alkaline base. Its vapor, however, is inflammable. There is also a diethylamin, $NH(C_2H_5)_2$, a triethylamin, $N(C_2H_5)_3$, and a tetrethylammonium, $N(C_2H_5)_4$.

Ethyl-Carbamides, or **Ethyl-Ureas,** compounds derived from carbamide or urea by the substitution of one

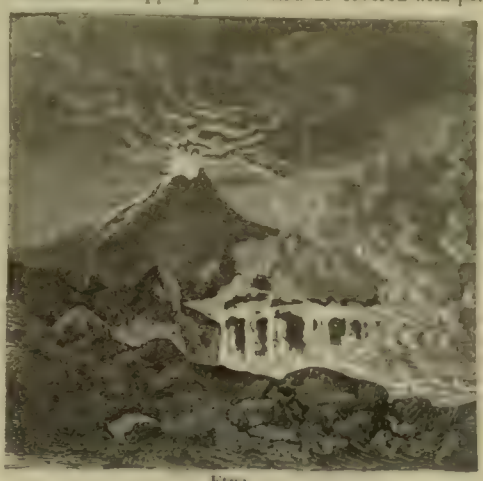
or more atoms of ethyl for a corresponding number of atoms of hydrogen.

Carbamide or urea $= N_2(CO)''H_4$.
Ethyl-carbamide $= N_2(CO)_2''(C_2H_5)H_3$.
Diethyl-carbamide $= N_2(CO)''(C_2H_5)_2H_2$.
Triethyl-carbamide $= N_2(CO)''(C_2H_5)_3H$.

Eth'ylene (C_2H_4), **Ethene, Olefiant Gas,** or **Bicarburetted Hydrogen,** produced by heating alcohol with strong sulphuric acid or boric anhydride; also by the dry distillation of many organic bodies, as fats, resins, wood, coal, many salts of organic acids, etc. It is an important constituent of coal gas, the illuminating power of which is largely due to its presence. It is a colorless gas, having a faint ethereal odor, which is attributed to a slight contamination with ether vapor. Its specific gravity is 0.9784. By pressure and cold it may be condensed to a limpid liquid. It burns in the air with a bright white flame which is very luminous. It is a diatomic radical, uniting with two atoms of Cl, B_2, Cy, and other monatomic radicals, and with one atom of O, S, and other diatomic radicals. By replacing hydrogen in two or more molecules of ammonia, it produces diamines, triamines, etc. (See ETHYLENE BASES.) Its compound with chlorine ($C_2H_4Cl_2$) has long been known as "Dutch liquid."

Eth'ylene Ba'ses. By the action of ethylene chloride, bromide, or iodide on ammonia, when heated in sealed tubes, Cloez, Nalanson, and Hofmann have shown that a series of compound ammonias are generated. When a molecule of ethylene replaces an atom of hydrogen in each of two molecules of ammonia, an ethylene diamine is produced, $C_2H_8N_2 = N_2\left\{\begin{matrix}H_2\\(C_2H_4)''\\H_2\end{matrix}\right.$. Two molecules of ethylene, replacing two atoms of hydrogen in each molecule of ammonia, yield diethylene-diamine. Three ethylenes, replacing all six atoms of H, yield triethylene diamine, $N_2(C_2H_4)''_3$. In the same manner, by replacements of hydrogen in three and four molecules of ammonia by ethylene, there are produced triamines and tetramines of various grades. The hydrogen remaining in the triamine or tetramine may be further replaced by the monatomic alcohol radicals, methyl, ethyl, etc.

Eth'ylene Car'bamides, or **Ethylene Ureas,** compounds produced by the action of cyanic acid and the cyanic ethers on ethylene-diamines. Ethylene-dicarbamide may be considered as formed of two molecules of urea or carbamide, in each of which one atom of hydrogen is replaced by a molecule of ethylene, thus: Urea $= N_2(CO)''H_4$; ethylene-dicarbamide $= N_4(CO)_2''(C_2H_4)''H_6 = N_2(CO)''\left\{\begin{matrix}\\\\\end{matrix}\right.(C_2H_4)''\left\{\begin{matrix}H_3\\H_3\end{matrix}\right.$.



Ethylenic Alcohols. By replacing two, four, six or more atoms of hydrogen in as many molecules of water, ethylene gives rise to a series of alcohols.

Etiola'tion [Fr. *étiolement*, from *étiolé*, "blanched"], the state of a plant which is deprived of green color by the exclusion of light. When it is obtained by keeping plants in the dark in order to render them tender and less acrid, it is called *blanching*, as in the case of celery.

Etiquette [from the Gr. ἦθος, plu. ἤθεα, "manners" or "morals," and the Fr. affix *ette*, meaning "little;" literally, "minute morals or manners"], the name given to the ceremonial forms required by good breeding to be observed in social or official life. Ceremonial observances were carried to the greatest extent by the Byzantine court, but the spirit of etiquette was probably never so tyrannical and predominant as at the court of Louis XIV.

Et'ive, Loch, in Scotland, is a salt-water lake or inlet of the sea in the county of Argyle. It is 20 miles long, and varies in width from half a mile to 3 miles. It receives the river Awe, and communicates with the Frith of Lorn. Grand and romantic scenery occurs along its banks.

Et'na [Gr. Αἴτνη; Lat. *Ætna*; Sicilian, *Mongibel'lo*], a celebrated volcanic mountain of Sicily, is in the N. E. part of the island, adjacent to the sea and very near to the city of Catania. It is an isolated mass of conical form, having no connection with the other Sicilian mountains, from which it is separated by the valley of the river Alcantara. It has an altitude of 10,935 feet above the level of the sea, and its base is about 90 miles in circumference. The volcanic phenomena which it presents on a greater scale than is elsewhere seen in Europe early attracted the attention of the ancients, and were described by Pindar, who mentions the rivers of fiery lava rolling down its sides into the sea. Thucydides informs us that an eruption occurred in 425 B. C. Four violent eruptions are recorded to have occurred in a period of twenty years—viz., 140, 135, 126, and 121 B. C. It appears that the volcanic action of Etna was in ancient, as it continues to be in modern times, irregular and intermittent. The city of Catania has repeatedly been nearly ruined by the eruptions and earthquakes. From the expressions of Strabo in his description of Etna, it is evident that in his time the ascent of the mountain to its summit was a common achievement. Several ancient writers describe the upper part of Etna as covered with perpetual snow, but at present the snow remains only eight or nine months of the year. Sir John Herschel, who ascended to the top of Etna in 1824, describes parts of its scenery in these terms: "Ascending from Catania, you skirt the stream of lava which destroyed a large part of that city in 1669, and which ran into the sea, forming a jetty or breakwater that now gives Catania what it never had before, the advantage of a harbor." "Among the remarkable features of Etna is that of its flanks, bristling over with innumerable smaller volcanoes. For the height is so great that the lava now scarcely ever rises to the top of the crater, for before that its immense weight breaks through at the sides." "From the summit," he adds, "extends a view of extraordinary magnificence." The last great eruption was in 1868.

Etna.

Etna, a township of Kosciusko co., Ind. Pop. 1007.

Etna, a township of Whitley co., Ind. Pop. 429.

Etna, a township of Hardin co., Ia. Pop. 1849.

Etna, a post-township of Penobscot co., Me., on the Maine Central R. R., 17 miles from Bangor. Pop. 844.

Etna, a post-village of Dryden township, Tompkins co., N. Y. Pop. 230.

Etna, a post-township of Licking co., O. Pop. of village, 258; of township, 1224.

Etna, a post-borough of Shaler township, Allegheny co., Pa. Pop. 1447.

Etna Green, a village in Etna township, Kosciusko co., Ind. Pop. 397.

E'ton, a town of England, in the county of Bucks, is on the Thames, opposite Windsor, 22 miles W. of London. It is the site of Eton College, one of the most famous educational institutions of England, founded and richly endowed in 1440 by Henry VI., but the buildings were not completed until 1523. It is a favorite school of preliminary instruction for the sons of the nobility and gentry. Many scholars are at the age of seventeen elected to valuable scholarships at King's College, Cambridge. Eton is governed by a provost and seven fellows. The main portion of the establishment, numbering nearly 900, consists of the *oppidans*, who live outside of the college, and for whose tuition the same price is paid as for that of the *collegers* or scholars. The number of the latter is limited to seventy.

Et'owah, a county in the N. E. of Alabama. Area, 650 square miles. It is intersected by the Coosa River. The surface is partly hilly; the soil is productive. Corn, wheat, cotton, tobacco, and wool are staple products. It is traversed by the Alabama and Chattanooga R. R. Capital, Gadsden. Pop. 10,109.

Etru'ria, or **Tuscia,** an important country of ancient Italy, was called **Tyrrhenia** (Τυρρηνία) by the Greeks. It was bounded on the N. by the Apennines, on the E. by the Tiber, and on the W. by the Mediterranean or Tyrrhenian Sea. The inhabitants were called Etruscans (*Etrus'ci*) and Tuscans (*Tus'ci*) by the classic Latin writers, but the Greeks always called them Tyrrhenians or Tyrsenians. Their national name in the Etruscan language was *Rasena*.

Among the physical features of this country are the Monte Amiata, which rises 5794 feet above the level of the sea, the

river Arnus (now Arno), and the Lacus Trasimenus, now called Lago Trasimeno or Lake of Perugia. Ancient writers concur in the statement that the government of the Etruscans was a confederacy of twelve cities or cantons, each of which was independent and had the right of internal self-government. The chief rulers bore the general title of *lucumo*. The cities which composed the league of Etruria Proper are universally reckoned as twelve in number, but these cannot be all identified, as no ancient writer has preserved a list of their names. Among the most important of these twelve cities were Tarquinii, Veii, Clusium, Volsinii, Cortona, Cære, Perusia, Arretium. The early traditions mention several Etruscan kings, as Porsena, king of Clusium, but during the greater part of the historic period the political constitution was an aristocracy. The Etruscans were very superstitious, and distinguished for their devotion to their national religion and the zeal with which they performed its rites and ceremonies (a word derived from *Cære*). The most important of the deities whom they worshipped were Tinia or Tina (Jupiter), Capra (Juno), and Minerva, whose name was the same in the Etruscan as in the Latin language. Besides these, and others whose names have been preserved, there were twelve divinities (six male and six female) whose proper names were unknown, but who were termed collectively *Dii Consentes*, and were counsellors of Tinia. They were believed to preside over the powers of nature. Superior to these, and to Tinia himself, were certain mysterious *Dii Involuti*, who were supposed to exercise an irresistible controlling power over the gods, like the Fates of the Greek and Roman mythology.

Origin and History.—The question of the origin and affinities of the Etruscans has long exercised the ingenuity of scholars and antiquaries, but it still remains undecided. The opinion generally adopted by Roman writers ascribed to them a Lydian origin. The earliest authority for this tradition is Herodotus, who states that he received it from the Lydians. This opinion was rejected by Hellanicus, who represents the Etruscans as Pelasgians, and by Dionysius of Halicarnassus, who considered them indigenous (*autochthones*), and states that in his time they were very distinct from every other people in language as well as manners and customs. Niebuhr maintained that they were a mixture of Pelasgians and Umbrians with a race of northern invaders (*Rasena*), who conquered the same at an unknown date. He believed that the Rasena or Etruscan nobility came originally from the Rhætian Alps. Our knowledge of the history of the Etruscans, even during the period of their greatest power and prosperity, is very vague and imperfect. The Etruscan language is thought to be Indo-European in its grammatical construction, though its vocabulary, so far as ascertained, cannot be with any certainty affiliated. There is no Etruscan literature extant, and no bilingual inscriptions of any length have been found. There were three Etrurian centres of occupation: (1) from the Tiber northward to Pisa, where the Etruscans seem to have been limited by the Ligurians; (2) the settlement on the Po, of which Bologna, Verona, and Mantua were the principal cities; the Etrurian population is shown by inscriptions to have extended northward to the Rhætian Alps; (3) that in the Phlegræan plains surrounding Capua and Nola, which are regarded as Etruscan cities. Livy informs us that before the Romans became the dominant people of Italy the power of the Tuscans was widely extended both by sea and land. Several Greek writers attest the facts that they were bold and enterprising navigators, and fitted out large fleets for naval warfare. In 538 B. C. they fought a naval battle against the Phocæans at Corsica. The Tuscans and Carthaginians were allies on this occasion, and in other battles against the Greek colonies of Italy. Besides the twelve cities of Etruria Proper, these people possessed another state or confederacy on the northern side of the Apennines. According to the Roman traditions, the Tuscans were a powerful nation before the foundation of Rome, 752 B. C. It probably attained its greatest power about 150 years later. The Tuscan cities of Clusium and Veii were involved in several wars against the rising power of Rome. Tradition indicates the establishment of an Etruscan dynasty at Rome under the later kings, the two Tarquins, and assigns to this period of Etruscan domination the construction of the Cloaca Maxima and the Capitol. About 508 B. C., Porsena, king of Clusium, marched against Rome, which the best critics think he captured. Hostilities continued, with occasional intervals, between the Romans and the Veientes from 483 B. C. to 396 B. C., when Veii was captured by Camillus and destroyed. It does not appear that the other Tuscan cities gave any aid to Veii during this period. This apparent neutrality may be explained by the fact that their northern frontier was then infested by predatory hordes of Gauls, whom they were scarcely able to repel. In the subsequent wars it was sometimes Tarquinii and sometimes Volsinii that fought against Rome. About 309 B. C. the combined forces of several Etruscan cities were defeated by Fabius Maximus in a battle which gave the first decisive blow to their power. The conquest was completed by a victory which the Romans gained at the Vadimonian Lake in 283 B. C. The Etruscans, however, retained long after this event their own language, customs, religious rites, and nationality. They were admitted to the Roman franchise in 89 B. C.

Arts and Civilization.—Ancient writers concur in representing the Etruscans as the most cultivated and refined people of ancient Italy, and as especially skilful in ornamental and useful arts. They often evince a singular similarity to Egyptian ideas and patterns which has astonished antiquarians. The Romans derived from them many arts and inventions that conduce to the comfort of life, besides the toga and other articles of dress, the curule chair, and the triumphal pomp. The genius of the Etruscans appears to have been practical rather than speculative. They excelled in agriculture, navigation, engineering, and in useful public works. They had made great progress in architecture, sculpture, and painting. The so-called Tuscan order of architecture is a modification of the Doric. The Cloaca Maxima at Rome proves that they were acquainted with the true principle of the arch, and exemplifies their skill in the construction of sewers. Of their temples, theatres, and amphitheatres no considerable remains have been preserved. Among the existing monuments of their massive and cyclopean masonry are fragments of walls which defended the cities of Cortona, Fæsulæ, Clusium, and Volaterræ. Their tombs present one of the most peculiar features in Etruscan antiquities. These are in some cases chambers hewn in a cliff or solid rock, and adorned outside with façades of temples. The interior walls are decorated with paintings, and the tombs contain vast numbers of vases, tripods, urns, etc. The Etruscans excelled in several branches of plastic art, especially in the fabrication of bronze articles and pottery. Bronze statues and utensils were exported from Etruria in immense numbers. Among the extant specimens of their bronze-work are the figure of a she-wolf in the Capitol of Rome, and the Chimæra in the Museum of Florence. It appears that the painted vases called Etruscan which have been found in great numbers especially at Chiusi (Clusium) and Vulci are Greek in design and workmanship. The metallic specula or mirrors, one side of which is adorned with figures, are peculiarly Etruscan, and are prized as illustrative of their customs, mythology, etc. (See K. O. MÜLLER, "Die Etrusker," 2 vols. 8vo, 1828; ABEKEN, "Mittel Italien," 1843; DENNIS, "Cities and Cemeteries of Etruria," 1848; INGHIRAMI, "Monumenti Etruschi," 7 vols. 4to, 1821–26; MICALI, "Storia degli Antichi Popoli Italiani," 3 vols., 1832), and the recent writings of Isaac Taylor and of Crawford on Etruscan Inscriptions.

Etruria, a township of Halifax co., N. C. Pop. 2938.

Etruria, Kingdom of, in Italy, was founded by Napoleon I. Mar. 21, 1801. Louis, duke of Parma (1773–1803), was the first king. His son Charles Louis succeeded him May 27, 1803, but Napoleon annexed the kingdom in 1807 to the French empire. Its capital was Florence.

Etruscan Language. See ETRURIA.

Etshmiadzin. See ECHMIEDZIN.

Et'tlingen, a town of Baden, on the river Alb and on a railway, 4 miles by rail S. of Carlsruhe. It has manufactures of gunpowder, cotton goods, and paper. Pop. in 1871, 5092.

Ett'müller (ERNST MORITZ LUDWIG), a German philologist and antiquary, born at Gersdorf, near Löbau, Oct. 5, 1802, studied at Leipsic and Jena. He became professor of German at Zurich in 1833, and gained distinction by his researches in mediæval German literature. He produced in 1844 an epic poem called "The Chiefs of the Royal German Houses" ("Deutsche Stammkönige"), and in 1852 an "Anglo-Saxon Lexicon." He also edited several old German poets.

Et'trick, a pastoral vale of Scotland, in Selkirkshire, extends along the Ettrick River, which, after a course of 28 miles, enters the Tweed 2 miles below Selkirk. It is remarkable for beautiful scenery. Ettrick Forest, a royal hunting tract, included all Selkirkshire. It is nearly divested of trees. James Hogg the poet, called the "Ettrick Shepherd," was born in the vale and parish of Ettrick.

Ettrick, a post-township of Trempealeau co., Wis. Pop. 1214.

Et'ty (WILLIAM), an English painter, born at York Mar. 10, 1787, was a pupil of Sir Thomas Lawrence. He was admitted as a student into the Royal Academy in 1806, and visited Italy in 1816. In 1821 he exhibited in the Academy "Cleopatra arriving in Cilicia." He was elected an acade-

mician in 1828. Among his works, which were greatly admired and brought high prices, are "Pandora Crowned by the Seasons" (1824), "The Combat: Woman pleading for the Vanquished" (1824), three pictures illustrating the acts of Judith (1827–31), "Joan of Arc" (1847), "The Judgment of Paris" (1826), and "Youth at the Prow and Pleasure at the Helm" (1832). He was an excellent colorist. Died Nov. 30, 1849. (See A. GILCHRIST, "Life of William Etty," 1855.)

Etymolog'icum Mag'num, a valuable lexicon or vocabulary of the Greek language by an unknown author. It is said to be the oldest extant Greek lexicon, and it contains many traditions respecting old and uncommon words. It is referred to the tenth century A. D. Editions of it have been published by Sylburg (1594), Schäfer (1816), Sturz (Leipsic, 1818), and Gaisford (Oxford, 1849).

Etymol'ogy [from the Gr. ἔτυμον, "literal sense," and λόγος, a "discourse"] is that branch of philology which traces the history of a word and of its grammatical variation from its primitive roots, and which shows the relationship of different languages by finding the same roots in these different languages. In grammar it is used in a more limited sense, as the name of that part of grammar which treats of the various parts of speech, the variations of declension, conjugation, etc. It is often used as nearly synonymous with the word "derivation." The study of the derivation of words is almost as old as civilization. Moses, Homer, and other very ancient writers often give explanations of the origin of proper names. Many tales of the Greek mythology give real or fanciful accounts of the appellations of gods and heroes. The Greek philosophers, the Alexandrian grammarians, the Roman Varro, and the later scholiasts wrote much upon the derivation of words, but to little purpose. They went to work with scanty information and with defective knowledge of the principles underlying a sound philology. Many of the derivations suggested by them are simply ludicrous, being suggested by mere resemblances of sound. Our knowledge of their labors is principally derived from the "Etymologicum Magnum" and "Etymologicum Gudianum," both probably written in the tenth century.

The revival of learning in the fourteenth century aroused anew the interest in etymological science; but it was not till the British occupation of India, and the beginning of the study of Sanscrit literature, that etymology received philosophical treatment. It is now known that the languages are properly regarded as members of greater or smaller groups or families; our own language being a member of the Teutonic group, which is itself a subdivision of the great Indo-European family, which comprehends many of the languages of Asia, and by far the greater number of those of Europe. A philosophic etymology seeks the derivation of words by judicious comparison of the vocabularies, the religious faith, the history, and the literature of nations ethnologically related, rather than by the comparison of words of any one or two languages.

The great etymologists are all modern, and are nearly all German, as is shown by the names of Adelung, Bopp, Pott, W. Humboldt, Grimm, Curtius, Benfey, and Schleicher. For Ugrian etymologies, the Finlanders Carsten and Ahlquist are high authorities.

Eu [Lat. *Au'ga* or *Augium*], a town of France, department of Seine-Inférieure, is about 20 miles E. N. E. of Dieppe and 5 miles from the sea. It has a fine Gothic church, and manufactures of lace, silk, and soap. Here is the château d'Eu, which was owned by King Louis Philippe, and is surrounded by a large and beautiful park. It contains a unique portrait-gallery, which is said to be the finest collection of historical portraits in France. Pop. in 1866, 4168.

Eu (PRINCE LOUIS PHILIPPE MARIE FERDINAND GASTON D'ORLÉANS), COMTE D', was born at the château of Neuilly, April 28, 1842, the eldest son of the duc de Nemours, and a grandson of Louis Philippe, king of the French. In 1864 he married Isabella, daughter of Dom Pedro II., emperor of Brazil. As marshal of the empire he took command of the allied forces operating against Paraguay, and Mar. 1, 1870, the war was ended by the death of the dictator Lopez, who was killed in a battle at Aquidubon.

Eubœ'a [Gr. Εὔβοια; Fr. *Eubée;* Turkish, *Egripo* or *Egripos;* It. *Negroponte*], formerly called **Negropont,** a Greek island, the largest island in the Ægean Sea, is about 90 miles long and comparatively narrow; the greatest breadth is about 30 miles. Area, 1574 square miles. It is separated from the N. E. coasts of Attica and Bœotia by the narrow channels of Egripo (*Euri'pus*) and Talanta. It is connected with the mainland of Bœotia by a bridge across the channel at Chalcis. The surface is mountainous. Mount Delphi, near the middle of the island, is said to be 7266 feet high. It is of limestone formation. The soil of the valleys is fertile, and produces cotton, wheat, grapes, etc. Among the exports are wool, hides, and oil. The chief towns are Chalcis and Carystus. In ancient times Eubœa belonged to the Athenian republic. It now forms a nomarchy of the kingdom of Greece. Pop. in 1870, 82,541.

Eubu'lides [Gr. Εὐβουλίδης], a Greek philosopher of the Megaric school, flourished about 350 B. C. He was a native of Miletus, a disciple of Euclid, and an adversary of Aristotle. He was the inventor of several sophistical syllogisms, including the *sorites*.

Eubu'lus [Εὔβουλος], an Athenian comic poet of the middle comedy, flourished about 375 B. C. He wrote numerous comedies on mythological subjects, of which only small fragments are extant. His language is elegant.

Eucalyp'tus (plu. **Eucalypti**), a genus of trees of the natural order Myrtaceæ, comprises numerous species, mostly natives of Australia. They form a characteristic feature of the peculiar vegetation of that island, having entire leathery leaves, of which one edge is directed towards the sky, so that both surfaces are equally exposed to the light. The *Eucalypti* are called "gum trees," because they abound in resinous exudations. The timber is excellent, and is used for shipbuilding and other purposes. The *Eucalyptus gigantea*, called "stringy bark," it is said sometimes attains a height of 480 feet and a diameter of 27 feet. Mr. George Robbins reports trees of this kind 500 feet high. They are probably the tallest trees on the globe. The bark of several species abounds in tannin, and is used for tanning leather. The *Eucalyptus resinifera*, which grows to a great height, yields a red astringent gum, which is called "Botany Bay kino," and is used in medicine as a substitute for kino. An exudation resembling manna in medicinal properties is obtained from the leaves of *Eucalyptus mannifera* and *dumosa*. The blue gum (*Eucalyptus globosa*) produces ship-timber of the best quality. It is said to furnish a febrifuge principle surpassing quinia in efficiency. Several species of *Eucalyptus* have been successfully introduced into California and Europe.

Eu'charist [Gr. εὐχαριστία, "the giving of thanks"], a name applied to the sacrament of the Holy Communion, or the feast of the Lord's Supper, in allusion to the blessing and thanksgiving with which the last supper of our Saviour with his disciples began and ended. This solemn festival has been kept in all Christian churches from the time of the resurrection, in commemoration of the passion and death of our Lord, and in obedience to his own divine institution. Among the earliest disciples in Judæa, the Lord's Supper seems to have been a regular meal, probably the principal meal of the day in each family, into which the commemorative breaking of bread and partaking of the cup of blessing were introduced as a part. Subsequently the disciples of many families came together and held a festival in common—a practice in which originated the ἀγάπη, or love-feast, in the course of which the brethren saluted each other with a holy kiss. The abuses which grew out of this, and which are severely rebuked by Saint Paul in the First Epistle to the Corinthians, led to a separation of the two institutions; and the commemorative observance has since been celebrated, with a solemnity in harmony with its character, by itself.

No part of the Christian practice and doctrine has given rise to larger diversities of opinion or to a more voluminous polemical literature than the sacrament of the Eucharist. These controversies were not known to the Church during its first eight or nine centuries. It seems entirely just to believe that, during all this early period, the visible elements employed in the celebration, the consecrated bread and wine, were regarded only as symbols and emblems of the body and blood of Christ given for our redemption; inasmuch as the expression of an opinion or doctrine different from this appears to have been first publicly made in the year 831 by a monk, subsequently abbot of Corbey in France, named Pascasius Radbert, who maintained the two following propositions, which he declared to be the true doctrine of the Church, but which were received with loud and general remonstrance: viz., first, that, "after the consecration of the bread and wine in the Lord's Supper, nothing remains but the outward figure, under which the body and blood of Christ are really and locally present"—that is to say, the doctrine more recently known under the name of *transubstantiation;* and secondly, that "the body of Christ thus present in the Eucharist is the same body that was born of the Virgin, that suffered on the cross, and that was raised from the dead." The excitement which followed this announcement was such that the emperor of Germany, Charles II. (I. of France, called "the Bald"), directed counter-expositions to be prepared by Johannes Scotus, and Ratramn (otherwise called Bertramn). The work of Scotus, though often cited in subsequent centuries, has perished; that of Ratramn is still extant. Both held that the consecrated bread and wine in the Eucharist are

only signs or symbols, and not the veritable body and blood of Christ; but in the work of Ratramn there are some things said on this point which are ambiguous or obscure, while Scotus, on the other hand, is said to have been perspicuous, distinct, and intelligible. Out of this dispute arose some extraordinary and repulsive secondary controversies, as to the natural consequences of taking into the stomach and digesting the consecrated elements, whatever view be taken of their nature, for which those who desire to understand them must refer to the ecclesiastical histories.

The doctrine of Pascasius, or at least his first proposition, found no small number of adherents, but the struggle, though warm, was a struggle of private opinions, and not of opinions with authority. The Church set forth no definition of her own views on the subject, and the excitement after a time abated. About two centuries later, however, the controversy was renewed in a manner which presently led to the interposition of the Roman pontiffs, and subsequently of councils of the Church. The first incident in this renewal was a declaration, in 1004, by Leutheric, archbishop of Sens, to the effect that none but the sincerely pious receive the body of Christ in the Holy Communion. It is easy to see what questions may arise out of a doctrine like this, especially with those who hold the certainty of the Real Presence. Later, in 1045, the celebrated Berenger, at that time archdeacon of Angers, taking the work of Johannes Scotus, above mentioned, as his text and guide, attacked with vehemence the doctrine of the Real Presence. He was met by Bruno, his own bishop (of Angers), and also by Hugh of Langres and Adelman of Bresse. But his most powerful and most dangerous antagonist was the pope, Leo IX., who assembled two councils in 1050—one at Rome and one at Vercelli—where he caused the writings of Berenger to be condemned and burned, and excommunicated their author. Retiring into Normandy, Berenger sought the support of William (afterwards "the conqueror" of England), but this prince having convened an assembly of the principal prelates and theologians of his province, the unfortunate polemist was again condemned; and in the Council of Paris, called by Henry I. in the same year (1050), he was not only condemned still a third time, but deprived of his benefices. The subsequent history of Berenger is a painful one. On three different occasions, under three different successive popes, Victor II., Nicholas II., and Gregory VII., he was compelled by threats and intimidation to renounce his opinions; and on two of these occasions, to subscribe to declarations drawn up for him by his enemies. The first of these declarations, made at what may be called his second trial, under Nicholas II., was to the effect that "the bread and wine after consecration are not only a sacrament, but also the real body and blood of Jesus Christ; and that this body and blood are handled by the priests and consumed by the faithful, and not in a sacramental sense, but in reality and truth, as other sensible objects are." This declaration he was not only forced to subscribe, but also to confirm with an oath; but hardly had he returned to France before he abjured it utterly, and resumed the teaching of his former views. He was accordingly arraigned a third time, and this arraignment took place under Gregory VII. (Hildebrand), who seems himself not to have partaken of the extreme views of Berenger's relentless persecutors, yet to have felt compelled to oblige him to renounce his own. The unfortunate man constrained himself consequently to subscribe to his belief of the following proposition, and to confirm this declaration by an oath—viz., that "the bread laid on the altar becomes, after consecration, the true body of Christ, which was born of the Virgin, suffered on the cross, and now sits at the right hand of the Father; and the wine placed on the altar becomes, after consecration, the true blood which flowed from the side of Christ." There was affirmed to be an ambiguity in this declaration, perhaps growing out of the construction to be put upon the words "laid, or placed, upon the altar." At any rate, it did not satisfy the enemies of Berenger, and he was therefore subjected to the humiliation of subscribing and making oath to still another confession of faith, in the following words—viz., that "the bread and wine are, by the mysterious influence of the holy prayer and the words of our Redeemer, substantially changed into the true, proper, and vivifying body and blood of Jesus Christ;" to which was added, that "the bread and wine are, after consecration, converted into the real body and blood of Christ, not only in quality of external signs and sacramental representations, but in their essential properties and substantial reality." This form of submission having been fully completed, Pope Gregory dismissed the humbled prelate with many marks of personal esteem, and visible and liberal evidences of his friendship. Notwithstanding which, no sooner was Berenger in his own country again, than he retracted this last declaration, as he had done all the former, and prepared an elaborate refutation of the doctrines to which he had just subscribed. The pope took no notice of this retractation, whence the inference has been drawn that Gregory himself was personally not far from entertaining the same opinions as Berenger. The evening of the days of this greatly tried champion of the right to freedom of opinion where the Church has not spoken, was passed in acts of penance and mortification, to which he subjected himself in expiation of the guilt of his dissimulation and perjury at Rome.

It was not till the assembling of the fourth Lateran Council by Innocent III., in the year 1215, that the voice of the Roman Church was authoritatively uttered as to the true doctrine of the Eucharist. That pope, through a decree of that council, declared the true faith to be that the elements of bread and wine are really and truly, after consecration, the body and blood of Jesus Christ in actual substance, remaining bread and wine only to outward appearance; and he himself invented and introduced the term "transubstantiation," by which this doctrine has been ever since known and recognized as a doctrine of the Roman Church. It was a natural consequence of the admission of this doctrine as an established dogma, that that view of the Eucharist which regards the ceremonial consecration and placing upon the altar of the elements, as a *sacrifice*, in which the original great sacrifice upon Calvary is perpetually renewed, found easy acceptance; and other consequences have been the worship of the consecrated elements, as being a worship directly paid to Christ himself; the elevation of the Host in the celebration of mass, that it may be seen and reverenced by the people; and the custom, prevalent in Roman Catholic countries, of carrying this consecrated bread about in solemn processions through the public streets, to be administered to the sick and dying.

Another controversy in regard to the Eucharist arose in the sixteenth century, which continues still to divide opinions, the Church not having formally declared on either side. It was (and is) held by the Jesuits and Dominicans, that the sacraments have in themselves an instrumental and efficient power, by virtue of which they work in the soul, independently of any previous preparation or state of the propensities, a disposition to receive the divine grace; and this they call the *opus operatum*. Thus, according to their view, neither knowledge, nor wisdom, nor humility, nor faith, nor devotion is necessary to the efficacy of the sacraments, whose prevailing energy nothing but a mortal sin can resist. Hence, therefore, according to them, priests may give immediate absolution to all who confess their misdeeds and evil thoughts and wicked sentiments and propensities, and admit them directly to the use of the sacraments. This view was resisted by the Jansenists, and is rejected by all in the Roman communion who have the progress of vital and practical religion truly at heart. These demand that none shall be admitted to the sacrament of the Holy Communion, who do not give evidence of true penitence, and of an intent henceforth to lead a new life, following the commandments of God, and walking in His holy ways.

The same century saw the great uprising against the abuses which had gradually crept into the Church of Rome, commonly called the Reformation, inaugurated by the monk Martin Luther. It soon appeared that, upon some essential points of doctrine, there was as little harmony of doctrine in the ranks of the Reformers, as there had been in those of the Church. In regard to the Eucharist, the difference between Luther and Zwingle, if not quite so wide, was at least as irreconcilable as that between the Jesuits and the Jansenists, or that of the ninth century between Radbert and Scotus. Luther maintained that the body and blood of Christ are really, though in a manner far beyond human comprehension, present in the Eucharist, and are exhibited together with the bread and wine. This is the doctrine since known as "consubstantiation." Zwingle, on the other hand, regarded the bread and wine as being only symbols present, and typifying the body and blood of Christ, which themselves are absent. Numbers of zealous and able men enrolled themselves in this controversy, on both sides, and the consequent danger to the common cause of Protestantism was such, that Philip, margrave of Hesse, whose devotion to this cause was deep and sincere, appointed a conference to be held at Morpung between Luther, Zwingle, and other doctors of both parties. The result, so far as the main point is concerned, was a failure. The two great leaders separated without either having been able to convince the other, and without having been able to agree upon any statement of doctrine in regard to Christ's presence in the Eucharist which both could accept.

The doctrine of the Anglican Church, which is that of the Episcopal Church in America on this subject, is briefly set forth in the catechism, where, after defining a sacrament to be an outward and visible *sign* of an inward and spiritual grace, and affirming the object for which the sacrament of the Lord's Supper was ordained to have been "for the con-

tinual remembrance of the sacrifice of the death of Christ, and of the benefits which we receive thereby," it is declared that in this sacrament the outward and visible part or sign is the "bread and wine which the Lord hath commanded to be received," and that the thing signified is "the body and blood of Christ, which are spiritually taken and received by the faithful in the Lord's Supper." And in the "Articles of Religion, as established by the bishops, clergy, and laity of the Protestant Episcopal Church in the United States of America, in convention, on the 12th day of September, in the year of our Lord 1801," which are, with some alterations of minor importance, identical with the Thirty-nine Articles of the Church of England, it is declared (in "Art. xxviii.; of the Lord's Supper") that "transubstantiation (or the change of the substance of the bread and wine) in the supper of our Lord, cannot be proved by Holy Writ; but is repugnant to the plain words of Scripture, overthroweth the nature of a sacrament, and hath given occasion to many superstitions." And further, "that the body of Christ is given, taken, and eaten in the Supper, only after an heavenly and spiritual manner. And the mean whereby the body of Christ is received and eaten in the Supper, is faith." F. A. P. BARNARD.

Euchee Anna. See UCHEE ANNA.

Euchlo'rine [from the Gr. εὐχλωρος, "bright green"], a name given to a green gas liberated when potassic chlorate is acted upon by hydrochloric or sulphuric acid. The gas is a mixture probably of chlorine (Cl) and perchloric oxide (Cl_2O_4). It possesses bleaching properties. It is prepared by heating gently a mixture of two parts of sulphuric acid, two of water, and one of chlorate of potash.

Eu'chre, a game of cards, originally German, but now a favorite in the U. S., chiefly as a social game. "Four-handed" euchre, where four persons are engaged, is the best form of the play, but two, three or even more than four persons may play, the rules being variously modified to suit such changes. Properly, two or four persons should play. The "euchre deck" contains the aces, the face-cards, and all spot-cards above the sixes, though many players reject all below the nines. In four-handed play the parties draw for deal, which falls to the one who draws the first jack. The right-hand adversary cuts, and the cards are dealt by threes and twos, or twos and threes, from left to right. The uppermost undealt card is turned for trump; the oldest hand "orders up" this card as trump if he sees fit; otherwise he "passes" to the next, who exercises the same choice, and so on. If not "ordered" or "taken" up the first time around, the players have in turn their choice of making a new trump or passing again. When a trump is "ordered" or "taken," the dealer may discard his poorest card, and take up the trump from the deck. The side which orders or takes up must take at least three tricks (one point), or lose two points (a euchre) to the other side. Four tricks also count one, but five tricks (a march) count two. In case one of the four players has a strong hand, he is at liberty to play alone, without his partner's help. In this case, if he makes a march, his side scores four; if he is euchred, the opposite side scores four. Five points make the game.

Another peculiarity of the game is, that the highest trump (right bower) is always the jack of trumps; the jack of the "next" suit—that of corresponding color—being always second best trump (left bower), the ace of trumps is third, the king fourth, etc. Jacks of a suit not trumps rank next below the queen of their suit. Euchre is an easy and simple game, and is consequently popular as a social pastime. Many varieties of it have sprung up, and at present almost every coterie has its own set of rules; some having a blank card for the highest trump, the bowers following; others allowing the victors to count on the next game all the points they have made above the five necessary to the victory, or allowing the possessor of a "lone hand" to call for his partner's best card, etc.

Euclase [from the Gr. εὖ, "good," "well," "easily," and κλάω, to "break," because it is so easily broken], a silicate of alumina and glucina which occurs in greenish crystals in Peru and Brazil. It is well adapted for jewelry, on account of its great hardness and the fine polish of which it is susceptible, but it is not much used as a gem in consequence of its rarity and fragility.

Eu'clid [Gr. Εὐκλείδης] OF ALEXANDRIA, a celebrated Greek, called the "father of geometry." He was born at Alexandria in Egypt, and lived about 300 B. C., and is said to have belonged to the Platonic school of philosophy. The events of his life are mostly unknown, except that he taught mathematics in the reign of Ptolemy I. (Soter), who died about 282 B. C. He made important discoveries in geometry, and surpassed all preceding geometers in the rigorous method and arrangement of his demonstrations. When Ptolemy I. asked him if geometry could not be mastered by an easier process than the ordinary one, he returned the celebrated answer, "There is no royal road to geometry." His "Elements of Geometry" present the most ancient system of that science that is extant, and have been considered an excellent standard work for 2000 years. (See SMITH, "Dictionary of Greek and Roman Biography.")

Euclid OF MEGARA, an eminent Greek disciple of Socrates, flourished about 400 B. C. He is said to have witnessed the death of Socrates (399 B. C.), after which he founded at Megara a school called the Megaric or Dialectic. His system was based on or partly derived from the principles of the Eleatic school, to which he added the ethics of Socrates.

Euclid, a post-village of Clay township, Onondaga co., N. Y. Pop. 138.

Euclid, a post-township of Cuyahoga co., O. P. 2188.

Eude'mus [Gr. Εὔδημος] OF RHODES, a Greek Peripatetic philosopher who lived about 320 B. C., was a disciple of Aristotle. He was a meritorious editor and commentator of Aristotle's works, and he wrote a "History of Geometry and Astronomy," which is not extant.

Eudiom'eter [from the Gr. εὖ, "good," and Διός, the genitive of Ζεύς, "Jupiter," regarded as the personification of the atmosphere, and μέτρον, a "measure"], an instrument originally intended for ascertaining the proportion of oxygen in the air, with a view of judging of its purity or impurity; but it is also employed to test the composition of any mixed gases. Many forms have been used, but one of the best consists of a graduated glass tube having two platinum electrodes within it, the tube closed at one end. To test the composition of air, for example, the carbon dioxide (carbonic acid) of the air within the tube is removed by strong liquor potassæ over a mercury bath, when the rise of the mercury within the tube indicates the proportion of carbon dioxide in the atmosphere. A large but determinate proportion of hydrogen is then introduced and exploded by means of the electrodes. After cooling, one-third of the loss of gas by explosion is the volume of free oxygen in the tube. Allowing for the hydrogen unconsumed, the volume of nitrogen is readily seen. The results are then reduced to a percentage of volumes.

Eudo'cia [Gr. Εὐδοκία; Fr. *Eudocie*], sometimes called **Eudoxia,** a beautiful Roman empress, born at Athens about 394 A. D. She was originally named ATHENAÏS, and assumed the name of Eudocia when she was converted to the Christian religion. In 421 she was married to the emperor Theodosius II. She was a woman of superior talents, and author of several poems. Having offended Theodosius and his sister Pulcheria, she was banished in 449, after which she resided in Palestine, and founded several convents in that country. Died in 460 or 461 A. D.

Eudo'ra, a post-village of Douglas co., Kan., on the Kansas River and the Missouri Pacific R. R., 8 miles E. of Lawrence. Pop. of Eudora township, 1901.

Eudox'us [Gr. Εὔδοξος], a Greek astronomer, born at Cnidos in Caria, flourished about 366 B. C. He was a pupil of Archytas and of Plato, and he opened a school at Athens or Cnidos. Cicero called him the prince of astronomers. Eudoxus computed the length of the year to be 365¼ days, and appears to have originated the doctrine of concentric solid crystalline spheres, by which he explained the apparent motions of the sun, moon, and planets.

Eufa'la, a township of Tallapoosa co., Ala. Pop. 595.

Eufau'la, a city of Barbour co., Ala., is on the right bank of the Chattahoochee River, which is navigable to this point for the largest boats at all seasons, 350 miles by river from Appalachicola, and 80 miles E. S. E. from Montgomery by the Montgomery and Eufaula R. R. It is the terminus of three railroads—the South-western Georgia, the Montgomery and Eufaula, and the Vicksburg and Brunswick. It has five churches, a Jewish synagogue, a female college, a school for colored people, and three private banking-houses, besides a building and loan and a savings bank and loan association, four cotton-warehouses, a public hall, a fair-ground, and one daily, one tri-weekly, and two weekly newspapers. Over 30,000 bales of cotton are sold here annually. Pop. 3185.

J. M. MACON, ED. "TIMES."

Eugene, a post-township of Vermillion co., Ind. Pop. of village, 347; of township, 1396.

Eugene, ū-jeen' [Fr. *Eugène*; Ger. *Eugen*], PRINCE, or, more fully, **François Eugene de Savoy,** a celebrated general, born in Paris Oct. 18, 1663. He was a son of Eugène Maurice, count of Soissons, and Olympia Mancini, a niece of Cardinal Mazarin. Having been offended by Louis XIV. of France, he entered the service of the emperor of Austria in 1683. He served with distinction in the war against the Turks, and was rapidly promoted. In 1691 he

obtained command of the imperial army in Piedmont, where he fought against the French. Louis XIV. afterwards offered him a marshal's bâton if he would enter the French service, but he declined. Having been appointed commander of the Austrian army in Hungary, he gained a decisive victory over the Turks at Zenta Sept. 11, 1697. In the great European war of the Spanish succession, which broke out in 1701, Eugene first commanded in Italy, where he was opposed by the able French marshal Catinat, and afterwards by Villeroi, whom he surprised at Cremona and took prisoner in Jan., 1702. An indecisive battle was fought at Luzara in Aug., 1702, by Prince Eugene and the duke of Vendôme. About the end of that year he was appointed president of the council of war in Vienna. He commanded the imperial army which co-operated in Germany with the English army under the duke of Marlborough. These allies defeated the French and Bavarians at the great battle of Blenheim, Aug. 13, 1704. In 1705 he took command of the army in Italy, and was defeated by the duke of Vendôme at Cassano in August of that year. He gained a victory over the French duke of Orleans at Turin in Sept., 1706, expelled the French from Italy, and returned to Vienna in 1707. The seat of war was next transferred to Flanders, where Prince Eugene was associated with the duke of Marlborough in the command of the combined armies. They defeated the French at Oudenarde (1708), and claimed the victory at the great battle of Malplaquet (Sept. 11, 1709), although they lost there about 25,000 men. In 1712 he was sent to London on a diplomatic mission, the object of which was to persuade the English to continue the war and to restore Marlborough to the command, but he was not successful. A victory which Marshal Villars gained over Prince Eugene at Denain in July, 1712, induced Austria to negotiate for peace. In Mar., 1714, he signed a treaty of peace at Rastadt. He defeated a large Turkish army at Peterwardein Aug. 5, 1716, and took Belgrade from the same enemy in 1717. After the end of this war, in 1718, he rendered important services as a statesman, and enjoyed the confidence of the emperor of Germany. He died in Vienna April 21, 1736. He was never married. Though he made no great improvement in tactics, he is reputed one of the greatest generals of modern times, being distinguished for his rapidity of perception, his decision, and his promptitude to rectify his errors. (See JOHN CAMPBELL, "Military History of Prince Eugene and Marlborough," 2 vols., 1736.)

Eugene City, the capital of Lane co., Or., is on the W. bank of Willamette River, here navigable for steamboats, and on the Oregon and California R. R., 71 miles S. of Salem. The State university is to be established here. It has two weekly newspapers. Pop. 861.

Euge'nia, a genus of trees and shrubs of the natural order Myrtaceæ, nearly related to the myrtle. It comprises numerous species, which are natives of tropical and subtropical countries, and some of them produce delicious fruits remarkable for their pleasant balsamic odors. The fruit is a berry of one or two cells, with one seed in each cell. The allspice or pimento of commerce is the unripe, sun-dried berry of the *Eugenia Pimenta*, which is indigenous in the West Indies. The *Eugenia Malaccensis*, a native of the Malayan Archipelago, is a small tree which bears a red fruit nearly as large as an apple, with a juicy pulp and an agreeable odor like that of a rose; hence it is called rose apple. The last name is also applied to the fruit of the *Eugenia Jambos*, an East Indian tree, now cultivated extensively in many tropical countries. The *Eugenia Ugni*, a native of Chili, has a small edible fruit, from which a refreshing beverage is obtained. Florida has five or more unimportant species.

Eugenia, a post-village of Grey co., Ontario, 28 miles from Collingwood. It is noted for its scenery. Here the Beaver River falls 334 feet in a mile, including a perpendicular descent of 70 feet. There are manufactures of lumber and woollen goods. Pop. about 100.

Eugénie, or, more fully, **Eugénie Marie de Montijo,** empress of France, was born at Granada, in Spain, May 5, 1826. Her father was the Spanish count de Montijo, and her mother was Maria Manuela Kirkpatrick, a woman of Scottish extraction. Eugénie was styled the countess of Teba in her youth. She was married to Napoleon III. in Jan., 1853, and bore a son in Mar., 1856. As a zealous Catholic she used her influence to promote the power of the pope. In Oct., 1869, she made a voyage to Venice, Constantinople, and Egypt, was present at the formal opening of the Suez Canal (Nov. 17), and returned to France at the end of November. After Napoleon put himself at the head of the army, about Aug. 1, 1870, she acted as regent until the people of Paris proclaimed a republic, Sept. 4, 1870. She then escaped to England.

Euge'nius I. was chosen pope in 654 A. D. as the successor of Martin I., who was banished by the emperor Constans. Died in 658.

Eugenius II., a native of Rome, succeeded Pascal I. as pope in 824 A. D. He called a council, which met at Rome in 826 for the reformation of the clergy. He died in 827, and was succeeded by Valentinus.

Eugenius III., a native of Pisa, was chosen pope in 1145, in place of Lucius II. The Romans, excited by the preaching of Arnaldo da Brescia, had revolted against Pope Lucius. Eugenius, being unable to enforce his authority, retired to France and held a council at Rheims in 1148. He also promoted the second Crusade. He died in 1153, and was succeeded by Anastasius IV.

Eugenius IV. (GABRIELE CONDOLMERO), a native of Venice, was chosen pope in 1431 as the successor of Martin V., who had convoked a council at Bâle. This council refused to recognize the supremacy of the pope. Eugenius therefore issued a bull proclaiming that the Council of Bâle was or must be dissolved, and he called another council at Ferrara in 1437. The Council of Bâle in 1438 deposed the pope, and elected as his successor Amadeus of Savoy, who assumed the name of Felix V. The result of this election was a schism in the Church, for Eugenius continued to act as pope in Rome, and was recognized by several powers. At the Council of Ferrara, Eugenius and John Palæologus signed in 1439 a convention for the union of the Greek and Latin churches, but this convention had no permanent effect. He died in 1447, and was succeeded by Nicholas V.

Eugu'bian Tables, the name of certain bronze tablets found near Gubbio (the ancient *Iguvium*) in 1444. Five of the inscriptions are in Etruscan and Umbrian characters, the other two in Latin. They were published by Lepsius in his "Inscriptiones Umbricæ et Oscæ" (1841).

Eula'lia, a post-township of Potter co., Pa. Pop. 353.

Eu'lenburg (FRIEDRICH ALBERT), GRAF ZU, a Prussian statesman, was born Jan. 29, 1815, went in 1859 as envoy extraordinary and minister plenipotentiary to China, Japan, and Siam, concluded (Jan. 1, 1861) a treaty of navigation with the government of Japan, and in September of the same year another with China. He became, Dec. 9, 1862, minister of the interior.

Eu'lenstein (KARL), born in Heilbronn, Würtemberg, in 1802, was apprenticed in youth to an ironmonger, who would not allow him to cultivate his musical tastes, which were naturally strong. As a last resort, he took up the Jew's harp, and, devoting his spare time to that instrument, he acquired such astonishing skill in playing it that his reputation extended throughout Europe.

Eu'ler (LEONARD), an eminent Swiss geometer, born at Bâle April 15, 1707. He was educated at the university of that city, and went to St. Petersburg with his friend Daniel Bernoulli. In 1733 he became professor of mathematics in the Academy of St. Petersburg. He displayed great fecundity and inventive genius by the composition of a multitude of treatises on mathematics. It is said that he wrote more than half of the forty-six quarto volumes published by the Academy between 1727 and 1783. Having been invited by Frederick the Great, he removed to Berlin in 1741. He improved the integral calculus and the science of mechanics. Among his numerous works are "Mechanics, or the Science of Motion analytically explained" (in Latin, 2 vols., 1736–42), a "Treatise on Naval Science" (1749), a "Treatise on the Integral Calculus" ("Institutiones Calculi Integralis," 1768), "Letters to a German Princess" (in French, 1768), a "Treatise on Dioptrics" (1771), and "Theory of the Moon's Motion" (1772). He became blind about 1767, after which he resided in St. Petersburg until his death, Sept. 7, 1783. Condorcet, who wrote a eulogy on him, says, "He multiplied his productions marvellously, and yet was original in each."

Eu'logy [Gr. εὐλογία, "praise," from εὖ, "good," and λόγος, "word;" Fr. *éloge*], an encomium pronounced on a person; a laudatory speech or written composition. In ecclesiastical history it was applied to a present bestowed on the Church after having been *blessed*.

Eu'lytine, Silicate of Bismuth, Bismuth-blende, a rare mineral found at Schneeberg in Saxony.

Eu'menes [Gr. Εὐμένης], a favorite officer of Alexander the Great, was born at Cardia, in Thrace, about 360 B. C. He had a high command in the army which Alexander conducted against Persia in 334 B. C., and gained the confidence of that prince. On the death of Alexander, Eumenes became governor of Cappadocia and Pontus. As an ally of Perdiccas he defeated Craterus in the year 321, soon after which Antigonus and Antipater formed a coalition against him. Eumenes was captured and put to death by Antigonus in 317 or 316 B. C. (See PLUTARCH, "Life of Eumenes.")

Eumen'ides [Gr. Εὐμενίδες (from εὖ, "good," and μένος, "mind," "disposition"), *i. e.* the "gracious ones," so called for the sake of propitiating them], or **Erinnyes,** the Greek name of the Furies, whom the Romans called Furiæ or Diræ. They were supposed to be goddesses who punished crimes and pursued the guilty with burning torches. According to the later tradition, there were three Furies—namely, Tisiphone, Alecto, and Megæra. The Cave of the Eumenides is at the N. E. angle of the Areopagus, immediately below the seats of the judges.

Eumol'pus [Gr. Εὔμολπος], a personage of the Greek mythology, was supposed to be a Thracian bard, a son of Neptune, and the founder of the Eleusinian mysteries. Museus is said to have had a son named Eumolpus, who was an instructor of Hercules.

Euna'pius [Gr. Εὐνάπιος], a sophist and physician, born at Sardis, in Lydia, about 348 A. D. He was a Neo-Platonist, an opponent of Christianity, and a partisan of Julian the Apostate. He lived at Athens, and wrote in Greek "The Lives of Philosophers and Sophists," which is highly prized. It was published by Boissonade in 1822. Died about 420.

Euno'mians, the followers of Eunomius, a strict Arian, who was made bishop of Cyzicus, in Asia Minor, in 360 A. D., but soon resigned on account of his theological opinions. The Eunomians were for a time very numerous, but the sect soon died out.

Euno'mius [Gr. Εὐνόμιος], the founder of an Arian sect called Eunomians, was born in Cappadocia. He was appointed bishop of Cyzicus in 360 A. D. by Eudoxius, bishop of Antioch, who afterwards deposed him for heresy. Eunomius was a man of superior abilities, and maintained the extreme Arian doctrines, for which he was several times banished. Died in 394 A. D.

Eu'nuch [Gr. εὐνοῦχος (from εὐνή, a "bed," and ἔχω, to "have" or "keep"), *i. e.* "having charge of the beds or chambers of the women"] was at first the title of servants who had the care of bed-chambers; and from the custom of placing women's apartments under the care of mutilated persons, the name came to be applied to the latter class exclusively. Mutilation was a very ancient practice, and was especially frequent in Syria and the East. It is a natural consequence of the system of polygamy. In Greece it was not common until the Byzantine period. In Rome under the emperors many eunuchs were kept. It is asserted that they were made to a considerable extent in mediæval Europe. In Italy they were formerly kept for their fine soprano singing. At present they are chiefly found in Mohammedan countries. At Moscow a community of eunuchs exists, who are jewellers by profession, and who add to their numbers by the purchase and mutilation of children. Eunuchs as a class are small, beardless, and weak, with a jealous, cowardly, and intriguing character; yet some, like Bagoas, the Persian minister, Philetærus, king of Pergama, and Narses, the Byzantine general, have possessed energy and ability. As used in the Bible and the classics, the word often means simply a chamberlain.

Euon'ymus [from the Gr. εὖ, "well," "propitious," and ὄνυμα, a "name," by euphemism because it is poisonous], a genus of shrubs of the natural order Celastraceæ, natives of Europe and the U. S. The fruit is a capsule, with seeds enclosed in a red aril. The flowers, foliage, and fruit of some of the species are poisonous. The wood of the *Euonymus Europæus,* an ornamental shrub, is strong, compact, and yellow, and is applied to various useful purposes. The *Euon'ymus atropurpu'reus* (burning bush or wahoo), a native of the U. S., is an ornamental shrub, with crimson fruit drooping on long peduncles. The bark is used as a remedy for dropsy and other diseases, and has active properties. The *Euonymus Americanus,* or strawberry bush, is often cultivated for ornament.

Eupato'ria, formerly **Koslof,** a seaport of Russia, in the government of Taurida, is on the Black Sea, and on the W. coast of the Crimea, 38 miles W. N. W. of Simferopol. It has a shallow harbor, a custom-house, a hospital, and a handsome Tartar mosque. Grain, wool, hides, and salt are exported from this place. The English and French armies landed here in Sept., 1854, and the Russians were repulsed here in Feb., 1855. Pop. 7730.

Eupato'rium [Gr. εὐπατόριον, said to have been named in honor of *Eu'pator,* a king of Pontus], a genus of plants of the natural order Compositæ, having the florets all tubular and perfect. It comprises many species of perennial herbs, mostly American. The *Eupato'rium perfolia'tum,* called boneset and thoroughwort, is a native of the U. S., and is used in medicine as a tonic, stimulant, and sudorific. The leaves, as the specific name denotes, are connate-perfoliate—*i. e.* united at the base around the stem. The hemp agrimony (*Eupato'rium cannab'inum*), which grows wild in England, has been used in medicine. The *Eupatorium purpureum* and several other American species appear to have valuable diuretic properties.

Eu'pen, oi'pen [Fr. *Nëau*], a manufacturing town of Rhenish Prussia, on the Vesdre, and in a beautiful valley 10 miles by rail S. S. W. of Aix-la-Chapelle. It is well built and flourishing, and derives its prosperity chiefly from its manufactures of woollen goods (broadcloths and cassimeres). It has fourteen woollen-mills, dyeworks, and manufactures of machinery. Pop. 14,696.

Euphemia, a post-village of Harrison township, Preble co., O. Pop. 107.

Eu'phemism [Gr. εὐφημισμός], a figure in rhetoric by which an unpleasant idea is expressed by indirect and milder terms. The euphemisms of the ancient heathens generally originated in a desire to deprecate the ill-will of malevolent powers, by attributing to them characteristics opposite to those which really belonged to them. Thus, the Furies were termed Eumenides, "gentle," by the Greeks.

Eu'phony [Gr. εὐφωνία, "goodness of voice" (from εὖ, "good," and φωνή, "voice")], agreeable sound; that quality in language which results from happy combinations of the enunciative elements, such especially as, though essentially different in their characteristic powers, easily melt into or blend with each other, so as to maintain an uninterrupted flow. It is the reverse of *cacophony.*

Euphor'bia [named in honor of *Euphor'bus,* physician to Juba, king of Mauritania], a genus of plants of the natural order Euphorbiaceæ, having an acrid, milky juice and monœcious flowers, included in a cup-shaped, four to five-lobed involucre resembling a calyx. Almost 100 species of this genus are natives of the U. S. An acrid drug called euphorbium is obtained from the *Euphorbia officina'rum* and from other species. Several species bear the popular name of spurge. The seeds of "caper spurge" (*Euphorbia Lathyris*) of Europe and the U. S. yield the fixed oil known as oil of euphorbia, a powerful cathartic. Some African Euphorbias are large trees.

Euphorbia'ceæ [from *Euphor'bia,* the typical genus], a large natural order of exogenous plants which abound in tropical America, and are found in nearly all parts of the globe. They mostly have an acrid and poisonous milky juice and diclinous or monœcious flowers. They may be distinguished from other diclinous orders by their tricoccous or 3-lobed fruit, and their definite suspended anatropous ovules. This order comprises, besides the EUPHORBIA (which see), the *Rici'nus* (castor-oil plant), the *Croton,* which yields croton oil, the *Sipho'nia,* from which caoutchouc is obtained, the *Bux'us semper'virens* (common box), and the *Jatropha Manihot,* the stem of which yields a nutritious food called cassava, manioc, or tapioca.

Euphor'bium, an acrid and inodorous gum-resin, is produced by the *Euphorbia officinarum* of Southern Africa and some other species, including *Euphorbia Canariensis* of Western Africa and *Euphorbia antiquarum* of the Levant. It is a violent emetic and purgative, and is sometimes used in the composition of plasters and in veterinary medicine.

Eupho'rion [Εὐφορίων], an Athenian tragic poet, was a son of Æschylus. He gained prizes with his father's dramas when Sophocles and Euripides were competitors.

Euphorion, an eminent Greek poet and grammarian, born at Chalcis in Eubœa, flourished about 250–220 B. C. He became librarian to Antiochus the Great. He produced epic poems entitled "Hesiodos," "Mopsopia," and "Chiliades," which were very popular; also several prose works. None of his works are extant.

Euphra'nor [Εὐφράνωρ], an eminent Greek painter and sculptor, born at Corinth, flourished about 350 B. C., and was a contemporary of Apelles. He excelled both in painting and in sculpture. Among his works, which are highly praised by Pliny and Plutarch, was a painting of the feigned insanity of Ulysses.

Eu'phrasy [Gr. εὐφρασία, from εὐφραίνω, to "delight"], or **Eyebright,** a plant of the order Scrophulariaceæ, the *Euphra'sia officina'lis,* a small annual herb from two to eight inches high, a native of Asia, Europe, and North America. Milton in his "Paradise Lost" speaks of its virtues in clearing the eyesight. It is not improbably somewhat useful in inflammation of the eyes, from its astringent character. Some varieties are said to have in their blossoms a spot or "signature" resembling the eye, and this spot caused, or at least strengthened, the popular faith in its powers.

Euphra'tes [Gr. Εὐφράτης: Turk. *El-Frat*], a large river of Western Asia, celebrated in all periods of history for the important events which have occurred on its banks, and the magnificence of the cities whose walls it washed. It rises in Armenia, in the Anti-Taurus Moun-

tains, by two branches—the Moorad and Kara-Soo—which unite near lat. 39° N. and lon. 39° E. The stream formed by this junction flows first south-westward, effects a passage through a defile of Mount Taurus, and forms the boundary between ancient Syria and Mesopotamia. Near the town of Bir it approaches within 100 miles of the Mediterranean. After crossing the 36th parallel of N. latitude it pursues a general south-eastern direction, flows through the extensive alluvial plains of Babylonia and Chaldæa, and enters the Persian Gulf at its north-western extremity. Its total length, says Guyot, is 1750 miles, and the area of its drainage is 255,000 square miles. It is navigable from Someisat to its mouth, 1195 miles. Its principal affluent is the Tigris, which is nearly as large as the Euphrates itself. It receives no large tributary from the right hand. The width in some places is nearly 600 yards, but below Hillah its volume and width are reduced by numerous canals cut for irrigation. The name Shatt-el-Arab is given by the natives to that part of the river below the mouth of the Tigris. The melted snows of the mountains of the Taurus and Anti-Taurus cause a periodical inundation of the Euphrates in the spring. The water is highest in May and June. In some parts of its course above Someisat the river passes through deep and narrow defiles or gorges between precipices nearly 1500 feet high, and presents much picturesque scenery. In ancient times the chief city on its banks was Babylon.

Euphros'yne [Gr. Εὐφροσύνη, from εὖ, "good," "easy," and φρήν, "mind"], one of the three Graces in Greek mythology, was supposed to be the daughter of Venus, and was a personification of the genius of mirth or joy.

Eu'phuism [from the Gr. εὐφυής, "graceful" (from εὖ, "good," and φυή, "growth," "form")], an affected style of speaking and writing which became a fashion in the reign of Queen Elizabeth. The term originated in the title of a pedantic romance called "Euphues" (1580), which was written by John Lilly (Lyly) and which abounded in affected conceits and extravagant antitheses. This style was ridiculed by Shakspeare and Ben Jonson.

Eu'pion [from the Gr. εὖ, "good," "very," and πίων, "fat," "rich," named in allusion to its oily nature], a limpid, inodorous, and oily liquid obtained by destructive distillation of various vegetable and animal substances, as coal, wood, oils, bones, etc. It is of a highly inflammable nature, dissolves in ether and alcohol, but is insoluble in water. Its specific gravity is 0.74, and it boils and evaporates at 340°. It consists essentially, according to Frankland, of hydrate of amyl, $C_5H_{11}H$.

Eu'polis [Εὔπολις], an eminent Athenian comic poet of the Old Comedy, was born about 446 B. C. He was a competitor of Aristophanes, whom, as some critics think, he surpassed in the charms of diction. Horace considered him worthy to be ranked with Cratinus and Aristophanes. Eupolis often satirized the persons and conduct of his eminent contemporaries, including Alcibiades. Died about 410 B. C. His works are lost except small fragments.

Eura'sians [contracted from *Europe* and *Asia*], or **Half-Castes,** is the name given in East India to the descendants of Europeans and Indian mothers, who are especially numerous in the large cities, as Calcutta, Madras, and Bombay. They generally receive a European education, but, although they speak the English grammatically, they have a peculiarly disagreeable pronunciation. The girls are often very beautiful, and generally marry English officers; while the young men enter the government offices or serve as clerks with merchants. They are very useful in this position, but as soon as they become rich, or advance to higher offices, they generally become insolent and wild. The Europeans, who also call them "Vepery Brahmins," do not hold them in high estimation. The natives call them "Tschitschi." Their number is estimated at 91,000.

Eure, a department in the N. W. part of France, is a part of the old province of Normandy. It is bounded on the N. by Seine Inférieure, on the E. by Oise and Seine-et-Oise, on the S. by Eure-et-Loir, and on the W. by Orne and Calvados. Area, 2301 square miles. It is intersected by the rivers Seine and Eure, and is bounded on the N. W. by the estuary of the former. The surface is mostly level; the soil is fertile. The staple productions are grain, hemp, flax, apples, and pears. Good horses, cattle, and sheep are reared here. Eure has important manufactures of cotton and woollen stuffs, paper, glass, stoneware, and copper-ware. Pop. in 1872, 377,874. Capital, Evreux.

Eure-et-Loir, a department in the N. W. part of France, is bounded on the N. by Eure, on the E. by Seine-et-Oise and Loiret, on the S. by Loir-et-Cher, and on the W. by Sarthe and Orne. Area, 2268 square miles. It is drained by the rivers Eure and Loir. The surface is partly level, and is in some parts diversified by hills and valleys. The soil is very fertile, and produces large crops of wheat. Good cavalry horses are raised here. This department is traversed by a railway connecting Paris with Chartres and Le Mans. Capital, Chartres. Pop. in 1872, 282,622.

Eure'ka, a post-village, capital of Humboldt co., Cal., is on Humboldt Bay, 7 miles from the ocean and about 225 miles N. N. W. of San Francisco. It has a safe harbor, with fifteen feet of water at low tide, and a daily and one weekly newspaper. Redwood lumber is largely shipped from this point. Pop. of Eureka township, 2049.

"Humboldt Times."

Eureka, a township of Nevada co., Cal. Pop. 1249.

Eureka, a township of Sierra co., Cal. Pop. 350.

Eureka, a post-village of Olio township, Woodford co., Ill., at the crossing of the Toledo Peoria and Warsaw and the Chicago Pekin and South-western R. Rs., 19 miles E. of Peoria. It has three churches and one weekly newspaper, and is the seat of Eureka College, connected with which is a normal school and a biblical school of the Disciples of Christ. Pop. 1233. E. Lowry, Pub. "Journal."

Eureka, a city, capital of Greenwood co., Kan., 110 miles S. S. W. of Topeka, in the centre of a fine grazing-region. It has one weekly newspaper, fine county buildings, public school-house, and five churches. Pop. of township, 1040. S. G. Mead, Ed. & Prop. of "Herald."

Eureka, a township of Montcalm co., Mich. P. 2775.

Eureka, a township of Dakota co., Minn. Pop. 924.

Eureka, a post-village of Lander co., Nev., is situated about midway between Salt Lake and San Francisco, and 80 miles S. of the Central Pacific R. R. The town will be connected by rail with the Central Pacific at Palisade, the branch, narrow gauge, being in course of construction. Eureka is the second town in importance in the State, Virginia City alone excelling it. The principal business is mining. It produces daily about 100 tons of lead and silver ore. It has one weekly newspaper. Pop. of Eureka district, 640. George W. Cassidy, Ed. "Sentinel."

Eureka, a post-village of Rushford township, Winnebago co., Wis. Pop. 317.

Eurip'ides [Gr. Εὐριπίδης], an eminent Athenian dramatist, and the latest of the three great tragic poets of Greece, was born in the island of Salamis in 480 B. C., or, according to the Arundel Marbles, in 485. According to a tradition, he was born on the day of the battle of Salamis, Sept. 23, 480. He was the son of an Athenian citizen named Mnesarchus, who sought refuge in Salamis when the Persian army captured Athens. He was a pupil of the great philosopher Anaxagoras, and he studied rhetoric under Prodicus. He also enjoyed the intimate friendship of Socrates. About 456 B. C. he produced "Peliades," the first of his dramas that was performed. As a rival of Sophocles he gained the first prize in several dramatic contests. His religious opinions were liberal, and excited the hostility of the conservative party, of which Aristophanes was the champion. Like Socrates, he was accused of impiety and unbelief in the gods. It appears that it was the violence and scurrility of these unscrupulous enemies that induced Euripides to remove from Athens about the year 408. He then retired to the court of Archelaus, king of Macedon, who treated him with kindness. Euripides composed seventy-five, or, as some say, ninety-two, tragedies, of which eighteen are extant—namely, "Alcestis" (438 B. C.), "Medea" (431), "Hippolytus" (428), "Hecuba" (424), "Heraclidæ" (421?), "Supplices" (421?), "Ion," "Hercules Furens," "Andromache," "Troades" (415), "Electra," "Helena" (412), "Iphigenia in Tauris," "Orestes" (408), "Phenissæ," "Bacchæ," "Iphigenia in Aulis," and "Rhesus." His style is remarkable for its brilliancy and pompous elegance. Among the warm admirers of Euripides were Aristotle (who calls him the most tragic of poets), Cicero, and Milton. "He was," says A. W. Schlegel, "a man of infinite talent and invention, possessed of the most varied intellectual accomplishments; but, although abounding in brilliant and attractive qualities, he wanted the sublime earnestness and artistic skill which we admire in Æschylus and Sophocles." According to a doubtful tradition, he was killed by hounds in 406 B. C., and buried at Pella. His works display great insight into human passions and skill in the analysis of character. Though his plots are censured as inartistic, he stands pre-eminent among the Greek tragic poets in the vigorous expression of individual passions and in knowledge of human nature. Among the best editions of Euripides are those of Musgrave, Oxford (4 vols., 1778), of Matthiæ, Leipsic (9 vols., 1813–20), of Kirchhoff, Berlin (2 vols., 1855), and of Nauck (2 vols.; 2d ed. 1857).

Euroc'lydon [Gr. εὐροκλύδων, from εὖρος, the "east wind," and κλύδων, a "billow"], the name of a violent wind of the Mediterranean, mentioned in Acts xxvii. 14. The Vulgate renders it *euro-aquila*, *i. e.* "north-east wind."

But in some of the best manuscripts (Sinaitic, Vatican, and Alexandrian) εὐρακύλων, "E. N. E. wind," is the reading, instead of εὐροκλύδων, "N. E. wind;" and this reading is adopted by the best recent editors. The wind in question is said to be half a point N. of E. N. E. (See SMITH'S "Voyage and Shipwreck of St. Paul," 1856; 3d ed. 1866.)

Euro'pa [Gr. Εὐρώπη], in classic mythology, a daughter of Agenor, king of Phœnicia, and a sister of Cadmus. According to the poetic legend, she was carried to Crete by Jupiter, who for that occasion assumed the form of a bull, and she was the mother of Minos and Rhadamanthus.

Eu'rope [Gr. Εὐρώπη; Lat. *Euro'pa;* by the ancients derived from *Europa*, a Phœnician princess; modern etymologists derive it from the Semitic word *erub*, "dark," thus representing Europe as the dark or mysterious country, as compared with Asia] is the fourth among the great divisions of the globe in point of extent, the second in point of population, and the first as regards density of population. For more than 2000 years it has marched at the head of the Old World in everything that relates to progress and civilization. Nearly the whole of Australasia, the larger portion of Asia, and a considerable part of Africa and America are the dependencies of European countries, and notwithstanding the rapid rise of the New World, it continues to be the foremost standard bearer of Christianity, for three-fourths of the entire Christian population of the globe live in Europe.

The superficial area of Europe is estimated at about 3,814,600 square miles. (See BEHM and WAGNER, "Bevölkerung der Erde," Gotha, 1872.) It is bounded on the N. by the Arctic Ocean, on the E. by Asia, on the S. by Asia and the Mediterranean Sea (which separates it from Africa), and on the W. by the Atlantic. The greatest extent of Europe is from S. W. to N. E., a line from Cape St. Vincent to the mouth of the Rara River measuring about 3400 miles, while the distance from Cape Nordkun, the northernmost point of Scandinavia, to Cape Matapan, the southern extremity of Greece, amounts to 2400 miles. The northernmost cape of Europe is the North Cape, on the little island of Mageroe, lat. 71° 11′ 40″ N. and lon. 25° 46′ E.; the southernmost, Cape Tarifa, lat 35° 59′ 57″ N. and lon. 5° 37′ W.; the connecting line between these two lines is 2406 miles long. The most western point is Cape la Roca, lat. 38° 46′ 30″ N. and lon. 9° 29′ W.; the eastern extremity lies in the Ural Mountains; the connecting line has 3200 miles. With the exception of a small tract reaching beyond the polar circle, the whole of Europe is situated in the northern temperate zone.

The coast-line of Europe is very fully developed, and it is more accessible from the sea-side than either Asia or Africa. The coast of its continent is estimated at 20,700 miles, of which about 2600 belong to the Arctic Ocean, 10,900 to the Atlantic Ocean, and 7200 to the Mediterranean and Black Seas. The bulk of Europe has the shape of an almost right-angled triangle, which covers about two-thirds of the entire area, and in the west more and more loses its continental character, and in its stead becomes oceanic. The points of the triangle are—to the S. W., the angular point of the Bay of Biscay; to the N. E., that of the Karskaia Gulf; and to the S. E., the northern extremity of the Caspian Sea. The proportion of the peninsulas to the main body is as one to four. The Arctic Ocean has only the small peninsulas of Kanin and Kola; Scandinavia, Jutland, Normandy, and Bretagne stretch into the Atlantic Ocean; the Pyrenean peninsula (Spain and Portugal) is washed by both the Atlantic and the Mediterranean, and forms the transition to Africa; the Balkan peninsula in the East connects with Asia Minor and the Crimea; the most south-eastern limb of the continent belongs to the Black Sea. The situation of the islands, which cover an area of 191,000 square miles (about one-twentieth of all Europe), is one very conducive to the progress of commerce and civilization. The most important of them are Great Britain, Ireland, the Balearic Islands, Sardinia, Corsica, Sicily, Malta, Crete, the Ionian Islands; Iceland, though it lies nearest to Greenland, is regarded as belonging to Europe, because from thence it has been peopled and civilized. Of the Portuguese possessions, the Azores and Madeira are generally included in the area of Europe. By means of a large number of navigable rivers and canals the inland countries to a large extent participate in the advantages of the maritime situation of Europe.

Political Divisions.—Politically, Europe was in 1873 divided into twenty sovereign states, of which three were empires (Germany, the Austro-Hungarian monarchy, and Russia), one a sultanate (Turkey, also sometimes counted among the empires), nine kingdoms (Great Britain, Portugal, Italy, Sweden, Norway, the Netherlands, Belgium, Denmark, Greece), one grand-duchy (Luxemburg), two principalities (Liechtenstein and Monaco), and five republics (Switzerland, San Marino, Andorra, France, and Spain). Four of these states (Liechtenstein, Monaco, San Marino, and Andorra) are so insignificant that many geographers do not enumerate them among the sovereign states. Luxemburg has the same ruler as the Netherlands, and Norway the same as Sweden; but, as they have nothing else in common, they must be counted as sovereign states. Germany and Switzerland are federal states, consisting, the former of twenty-six states (three of which are free cities), and the latter of twenty-two cantons, which have ceded part of their sovereignty to the central power of the federal state, but reserved to themselves the sovereignty in all points not expressly ceded. A large majority of the European states are monarchies, but only Turkey is a despotism. Since 1848 absolutism has steadily been losing ground, and in nearly every European country the sovereign shares the legislative function with a representative body, which in some is elected by universal suffrage. In one monarchy (Norway) the king has only a suspensive veto. Republican tendencies are at work in nearly every monarchy of Europe; and as they have been successful in France in 1848, and again in 1870, and in Spain in 1873, they are expected to extend ere long the territory of republicanism at the expense of monarchical institutions.

The following table exhibits the area and population of each sovereign country of Europe at the beginning of 1873:

Countries.	Sq. Miles.	Population.
German empire	208,619	41,058,139
Austro-Hungarian monarchy	240,348	35,904,435
Principality of Liechtenstein	62	8,820
Republic of Switzerland	15,992	2,669,147
Kingdom of Denmark (inclusive of Faröe Islands and Iceland)	55,020	1,864,496
Kingdom of Sweden	170,392	4,168,525
Kingdom of Norway	122,280	1,753,000
Kingdom of the Netherlands	12,680	3,688,337
Grand-duchy of Luxemburg	999	197,504

Kingdom of Greece	19,353	1,457,894
Total	3,787,178	301,605,227

With regard to their size, population, and power, the states of Europe are divided into states of the first, second, third, and fourth class. To the first class belong Great Britain, France, Germany, Austria, Russia, and Italy. Their aggregate area and population is more than double the area and population of all the remainder of Europe. They are therefore commonly called the "great powers of Europe." Whenever they agree on international questions their agreement is the law of Europe; and they frequently hold international conferences to avert, if possible, impending wars. Nine of the European states (Great Britain, Turkey, the Netherlands, Russia, Spain, France, Portugal, Denmark, and Sweden) have possessions in other divisions of the world, the aggregate area of which is nearly five times as large as that of all Europe, while their population (250,000,000) does not quite reach that of Europe.

Physical Geography.—With regard to its orographic condition, Europe may be divided into two large, unequal portions. North-eastern Europe is a vast plain of great uniformity, while South-western Europe is a table-land, but frequently intersected by small plains, and therefore presenting considerable variety. The table-land of Europe is estimated at over two-sevenths of the entire area, while not quite five-sevenths consists of plains. The central table-land of Europe contains a vast triangle of mountains, the system of the Alps forming the base, and the European Middle Mountains furnishing the sides. The principal portions of the latter are the French Middle Mountains, the highest point of which is Mont Dore; the German Middle Mountains, with the Riesengebirge as the highest range; and the Carpathian Middle Mountains, which reach their highest point in the Gerlsdorfer Spitze. The system of the Balkan, which traverses Turkey and Greece, and the Apennines of Italy, are also connected with the Alps, while the Pyrenees, the mountains of the Iberian and the Scandina-

vian peninsulas, as well as those of the British and other islands, are isolated masses. The character of the European mountains, in comparison with those of other large divisions of the globe, is more distinguished for a variety of combinations than for grand developments. The mountains yield, on the whole, but small amounts of the precious metals, while, in accordance with the prevailing feature of the physical geography of Europe, the useful metal, iron, is found in very large quantities.

The hydrographic relations of Europe are characterized by abundance and variety. Europe has no river-system of such colossal dimensions as are found in Asia and America, and the largest European river, the Volga, sends its water eastward to the Caspian Sea, which Europe has in common with Asia. On the other hand, the rivers of Europe are more advantageously distributed than those of any other large continent. They penetrate every part of it, fertilize every country, and give to each a considerable share in its flourishing commerce and industry. These advantages are still further increased by the numerous canals which the fortunate formation of the soil has allowed to be constructed for the connection of the large rivers. The largest number of European rivers flow into the Atlantic Ocean, which receives the Tornea in Sweden, the Neva, Duna, Niemen, and Pregel in Russia, the Vistula, Oder, Elbe, Weser, Ems in Germany, the Rhine and Scheldt in the Netherlands and Belgium, the Thames and Severn in England, the Seine, Loire, Garonne in France, the Duero, Tagus, Guadiana, and Guadalquivir in Spain and Portugal. The Ebro in Spain, the Rhone in France, the Arno, Tiber, Po, and Adige in Italy, flow into the Mediterranean; the Danube, Dniester, Dnieper, and Don into the Black Sea; the Volga into the Caspian; and the Petchora and the Dwina into the Arctic Ocean. In inland lakes Europe is richer than any other great division of the globe except North America. The lakes group themselves around two centres, the Baltic Sea and the Alps. To the former class belong the Ladoga and Onega lakes, the largest fresh-water lakes of Europe.

The following parts of Europe, according to the map in Lyell's "Principles of Geology," consist chiefly of primitive or transition formations: The Uralian Mountains in Russia; nearly the whole of the Scandinavian peninsula; most of Scotland, one-half of Ireland, the western part of Wales, the northern counties and Devon and Cornwall in England; a large portion of Northern and Central France; the high ranges of the Alps; a large portion of Central Italy and of the adjacent islands (Corsica, Sardinia, and Sicily); of the Austro-Hungarian monarchy, Bohemia, Carinthia, Styria, parts of Hungary, and Transylvania; the eastern half of the Balkan peninsula and the central chain of the Caucasus. The parts principally composed of secondary formations are—in the British Isles, the Lowlands of Scotland, the centre of Ireland, the north-eastern, central, and most of the southern counties of England; most of France and Western Germany; the loftiest summits of the Pyrenees; Southern and part of Central Italy; of the Austro-Hungarian monarchy, Istria, Dalmatia, Galicia, and the eastern districts of Transylvania; of Russia, some extensive tracts on the Volga and Kami, and the northern declivity of the Caucasus. The remainder of Europe—in particular most of Russia and Prussia, all Denmark, North-western Germany and Holland, a large portion of Belgium, the northern part of Switzerland, the basins of the Loire, Rhone, and Garonne in France, the plains of Lombardy, Hungary, Wallachia, and Bulgaria—is chiefly occupied by tertiary, alluvial, and diluvial formations. Granite, gneiss, and syenite are among the chief primary rocks of the great tableland of Europe. Gneiss is the rock in which the Saxon, Bohemian, and Austrian metallic mines are principally situated, while granite abounds in most of the countries where primary formations are found. Active volcanoes at present are only met with in Italy (Stromboli, Vesuvius, and Etna) and Iceland, but there are traces of former volcanic activity in France, Greece, Germany, and other countries. Of mineral springs Europe has an abundance and a great variety.

Europe is the only one among the great divisions of the globe which nowhere touches the torrid zone, and only a comparatively small portion extends about 280 miles into the northern frigid zone. The bulk of the continent belongs to the northern temperate zone. The climate of Europe is a mixture of the continental and the oceanic, and is throughout more temperate than in non-European countries of equal latitude. In North-eastern Europe the continental climate prevails, with its clear sky and dry air, while Southern and South-western Europe have more an oceanic, uniform, and mild climate, with humid air and frequent winter rains. The extremes of temperature are −58° and 106° Fahrenheit.

In the geography of European plants four zones may be distinguished: 1. The northern zone embraces Iceland, the Scandinavian peninsula north of 64°, and Russia north of 62°. The vegetation of this zone is poor. Lichens and mosses are frequent; the only species of grain to be found are oats, rye, and barley, the two former only along the southern margin of the zone, but barley up to 70°. The forests consist of birches and firs, but they are crippled N. of 64°. 2. The northern middle zone, extending southward to 51° and 48°, comprises the British Isles, Denmark, Southern Scandinavia, Finland, Central Russia, Northern France, Belgium and the Netherlands, Northern Germany and Italy. Besides the species of grain found in the northern zone, wheat is also found. Buckwheat, potatoes, leguminous plants, hemp, flax, and many kinds of northern fruit, as apples, pears, cherries, etc., are extensively cultivated. The beech and the oak prevail in the forests. 3. The southern middle zone extends southward to the Pyrenees, the Alps, and the Balkan. Southern France, Switzerland, Southern Germany and Lombardy, the Carpathian countries, the larger portion of Turkey and Southern Russia, belong to this zone. The mountains have forests of pine trees; the plains, oaks, beeches, and chestnut. Wheat and wine are extensively grown. 4. The southern or evergreen zone, embracing the three southern peninsulas and the southern coast of France. The vegetation of this zone is luxurious; it is noted for its olives and evergreen woods and its fiery wines. The orange flourishes in the southern portion of it, and rice is cultivated in Northern Italy and Eastern Spain.

The character of the European fauna fully corresponds to the physiognomy of the continent. Vast formations are wholly wanting. The class of rapacious animals has its largest representatives in the wolf, lynx, and bear. The number of reptiles is small. On the other hand, the domestic animals are more largely extended and more improved in Europe than in any other country of the world. Peculiar to the north of Europe is the reindeer. The birds are inferior to those of other divisions in their size and brilliancy of color, but are noted for the sweetness of their voices and their melodious songs. Northern Europe has a larger number of species of animals, but the south has a larger number of individuals. The northern seas, lakes, and rivers have a larger abundance of fish than those of the south.

Population, Races of People, Language, and Religion.—The entire population of Europe at the beginning of the year 1873 amounted to 300,800,000. The vast majority of the inhabitants belong to the Caucasian race; only about one-nineteenth are Mongolians. The Caucasian race comprises in Europe three large groups, which conjointly constitute the bulk of the population, and several fragments of nations which, in former times widely extended, are now reduced to small limits. The three large groups are the Germanic, the Greco-Romanic, and the Slavic. The Germanic is subdivided into the Germans proper, inclusive of the Dutch, Frisians, and Flemish (about 56,500,000), the Scandinavians (8,000,000), and the Anglo-Saxons or English (about 20,500,000), in all, 94,000,000, or 31.2 per cent. of the population of Europe. The whole of Germany, Holland, Denmark, Sweden, Norway, Great Britain is occupied by the Germanic race, which also prevails, as to influence, in the western half of Austria and the Baltic Provinces of Russia; as regards number, in Belgium; and as regards both influence and number, in Switzerland. The Greco-Romanic group occupies the south and the south-west of Europe. The chief nationalities belonging to it are the French, 41,260,000; Italian, 27,620,000; Spanish and Portuguese, 16,320,000; Daco-Rumanian and Macedo-Wallachian, 8,100,000; Greek, 2,450,000; and Albanians, 1,440,000; in all, 97,200,000, or 32.3 per cent. of the entire population. It controls the destinies of France, Spain, Portugal, Italy, seven cantons of Switzerland, Greece, and Rumania; it predominates in several provinces of European Turkey, Southern Hungary, and Transylvania; and its influence prevails in Belgium, though it does not form the majority of its population. The Slavic group, though in numbers somewhat inferior to the Germanic and Greco-Romanic, and containing only 27.3 per cent. of the aggregate population of Europe, occupies fully three-fifths of its area. Its chief branches are the Russians and Ruthenians, 54,530,000; the Poles, 9,420,000; the Czechs and Wends, 6,900,000; the Servians, Croatians, and Sloventzi, 7,200,000; the Bulgarians, 4,080,000. It rules in only one large sovereign country, Russia; to which may be added the principality of Montenegro and the semi-independent principality of Servia; but both in the Austro-Hungarian monarchy and in European Turkey it constitutes a plurality of the population, and even in the formerly Polish districts of Prussia it constitutes a compact population of over 2,000,000. Besides these three large groups, the Caucasian race also embraces the remnants of the Celts, Lithuanians, and Iberians or Basques. The Celts, who at one time ruled in Northern Italy, France, and the British Isles, now only linger in French Bretagne, in Wales, Ireland, and High Scotland. In France their language is still spoken by a population of

1,100,000, and in the British Isles by about 2,300,000. The Lithuanians, embracing the Lithuanians proper, the Letts, and the Prussians, live on the Baltic Sea, and number 2,900,000, while the Basques, the descendants of the aboriginal inhabitants of Spain, live in the Western Pyrenees, and have been reduced to about 1,000,000. To the Semitic race belong about 5,000,000 Israelites, who are scattered throughout Europe. There are also a few hundred thousand Gypsies. A branch of the Mongolian race, the Finns, which was formerly spread over a vast area, includes the Finns proper, the Esthonians and Livonians, the Lapps, the Samoyedes, and other tribes on the Arctic Ocean, and, as far as the language is concerned, also the Magyars, who by some ethnographic writers are classed as a branch of the Mongolians different from the Finns. These Finnish tribes number in all about 10,000,000. Whether the Turks belong to the Mongolian or to the Caucasian race is still a matter of dispute, though most writers regard them as Mongolians, and explain the Caucasian features which have been observed by their mixture with the Caucasian tribes living near and among them. The Calmucks of Russia are another Mongolian tribe.

Religion.—The entire population of Europe, with the exception of 5,000,000 Jews, 6,800,000 Mohammedans, and 500,000 Pagans in Russia and Turkey, belongs to Christianity, which by doctrinal differences is split into three main divisions—the Roman Catholic, the Orthodox Greek, and the Protestant churches. By far the largest population belongs to the Roman Catholic Church, to which the overwhelming majority of the Greco-Romanic nations also adheres, as well as nearly one-half of the Germanic; the Poles, Czechs, Croatians, Slovacks, Ruthenians, among the Slavi; the majority of the Magyars, the Lithuanians, the Celts of Ireland and France, and the Basques. It comprises more than 98 per cent. of the population in Spain, Portugal, Italy, Belgium, Luxemburg, and France; 92 per cent. in Cisleithan and 59 in Transleithan Austria; from 40 to 36 per cent. in Switzerland, the Netherlands, and Germany; 17½ per cent. in Great Britain and Ireland; and less than 10 per cent. in every other country of Europe. The aggregate population connected with it was estimated in 1872 at 147,700,000, or over 49 per cent. of the population of Europe. The Orthodox Greek Church (with a population of 69,200,000, or 23 per cent. of all Europeans) embraces the large majority of all the Slavic tribes and the Greeks and Rumanians of the Greco-Romanic. It constitutes about 99 per cent. in Servia, 97 in Greece, 95 in Rumania, 85 in Russia, 48 in Turkey, and 17 per cent. in Transleithan Austria. Protestantism, which is subdivided into a number of religious denominations, has its stronghold in the Germanic countries, where more than one-half of the entire population belongs to it. Sweden, Norway, and Denmark are almost entirely Protestant (over 99 per cent. of the total population); in Great Britain and Ireland the Protestant population is estimated at 83 per cent., in Germany at 62, in the Netherlands at 61, in Switzerland at 59. Outside of the Germanic world Protestantism also prevails in the grand duchy of Finland (97.7 per cent.), among the Letts in the Baltic Provinces of Russia, and among the Celts of Wales and Scotland.

History.—The authentic history of the European states begins with the tribes of Greece, which also occupied the coast of Asia Minor, and which, after founding a number of flourishing commonwealths in the territory of the modern kingdom of Greece and the southern part of modern Turkey, vied with the Phœnicians in establishing flourishing colonies on the coasts of the Mediterranean and the Black Sea. But they never succeeded in founding a powerful state, which, for the first time in Europe, was done in the fourth century B. C. by Alexander the Great, whose achievements were, however, of comparatively little influence on the destinies of Europe, as they mostly concerned Asia, and as his world-empire collapsed at his premature death. Of more lasting influence was the rise of the Roman republic, which in Europe annexed not only the whole of Italy, but Greece, Gaul, Spain, and portions of Germany, Britain, and Eastern Europe, and which, by consolidating a large portion of Europe under one rule, contributed considerably to the rapid spread of the Christian religion. (See the Map of Europe under the Romans.) Under the emperors the vast extent of the state was not only preserved, but even enlarged; but with the increase of territory also increased the corruption of the masses and the weakness of the government, which at the close of the fourth century of the Christian era found itself no longer able to resist the onset and invasion of the vigorous but barbarian tribes of Germans and Mongolians. In 476 the Western Roman empire succumbed to the attack of the German prince Odoacer, and was shattered to pieces, many of which, in Italy, Spain, Gaul, and Britain, were reconstructed as Germanic kingdoms. Under the Merovingians the kingdom of the Franks became the predominant power in Central Europe, and under Charlemagne the incorporation with it of nearly the whole of modern Germany made it the great Christian empire of the globe, whose rulers on that account appeared to be well entitled to the revived title of Roman emperor. (See the Map of Europe under the Carlovingians.) About the same time the union of the smaller divisions of Britain laid the foundation of the kingdom of England, and in North-eastern Europe the first Slavic states were organized. The empire of Charlemagne was divided by his grandsons into France, Germany, and Italy, and though for short intervals the whole empire was reunited in one hand, these divisions, to which for several centuries a kingdom of Burgundy was added as the fourth, became permanent. In Spain, where the Mohammedans had established on the rdins of the Christian kingdoms of the Germanic tribes the powerful and flourishing caliñate of Córdova, the Christians, who at the time of Charlemagne only maintained themselves with difficulty in the north-western kingdom of Asturias, gradually gained ground in the tenth and eleventh centuries, and at the time of the Hohenstaufens, in the twelfth century, had reconquered more than one-half of the Peninsula and reconstructed it into several Christian kingdoms. In Eastern Europe the Slavi organized the large Christian empires of Poland and Russia in North-eastern, and the smaller states of Servia and Bulgaria in South-eastern, Europe, and even the large kingdom founded by the Mongolian tribe of Magyars became Christianized. While thus the division of Europe into independent states became perpetuated, the Christian religion became a powerful bond of union, notwithstanding the split into the Eastern (or Greek) and the Western (or Roman) Catholic churches. The theocratic supremacy which several great popes like Gregory VII. and Innocent III. succeeded in establishing over all the states belonging to the Roman Catholic Church, created the consciousness of a community of interests, which found its strongest expression in the Crusades. In Eastern Europe the Eastern Roman or Byzantine empire, which ever since the division of the Roman empire into an eastern and a western half, had gradually been declining in extent and influence, was shaken to its foundation by the invasion of the Turks, who finally (in 1453) conquered Constantinople and established a Mohammedan despotism. On the other hand, the Mohammedans constantly lost ground in the Pyrenean peninsula, until at the close of the fifteenth century their last stronghold was conquered. At the same time Russia succeeded in throwing off the yoke of the Mongolians, in driving them back to Asia, and in building up a powerful Christian empire in the east of Europe. Thus the whole of Europe, with the single exception of the Balkan peninsula, which had fallen under Mohammedan rule, was occupied by Christian nations, which during this period, by circumnavigating Africa, by gaining a firm footing in Southern Asia, and by discovering and conquering America, greatly extended the influence of European civilization and of the Christian religion over the other great divisions of the globe. The religious Reformation of the sixteenth century added another to the two large divisions which had existed in the Christian Church since the ninth century. England, the Scandinavian kingdoms, the Netherlands, and a number of the German states and Swiss cantons seceded from the Roman Catholic Church, and established new forms of religious organization. Several wars, among which the Thirty Years' war (1618–48) was the most terrible, sprang from this ecclesiastical separation; but the revolt against the spiritual authority, which demanded from all minds (and enforced as much as it could) absolute submission to its decrees, and the emulation between the states embracing the new form of religion and those adhering to the old Church, gave a powerful impulse to the progress of civilization, literature, and art, and in particular to free political institutions.

The two most powerful princes of Christendom, the emperor of Germany (who was at the same time king of Spain) and the king of France, both repelled the Reformation and remained in connection with the Church of Rome; and when the power of the former became more and more neutralized by the growing independence of the princes, one-half of whom were Protestants, the emperors of Austria—who since 1526 had united the lands of the Hungarian crown with their own dominions, and who, with only one short interval, remained German emperors until the dissolution of the empire in 1806—became the steadfast and influential patrons of the interests of the Catholic Church. But the union of Scotland with England established at the beginning of the sixteenth century the first Protestant great power of Europe, and the kingdom of Prussia, which was founded in 1701, fully established by the Seven Years' war (1756–63) its claim to be regarded as the second. The same rank could now no longer be re-

fused to Russia, which had snatched from Sweden its possessions on the Baltic Sea, and extended its rule far into Asia. Another large country of Eastern Europe, Poland, which under more favorable circumstances might likewise have become one of the great powers of Europe, was at the close of the eighteenth century dismembered and divided between Prussia, Russia, and Austria, after its vitality had long been fully exhausted by chronic anarchy. The ascendency of France, Austria, Great Britain, Prussia, and Russia, as the five great powers of Europe, was thus fully established when the French Revolution of 1789, and still more the empire of the first Napoleon, which arose out of its ashes, shook the whole system of European states to its foundation. The subjection, direct or indirect, of Spain, Portugal, Italy, the Netherlands, Switzerland, and a large portion of Germany to the rule of Napoleon (see the Map of Europe under Napoleon I.) appeared to usher in a new world-empire; but his downfall in 1814 and 1815 restored, on the whole, the frontiers of the European states as they existed before the Revolution. The five great powers reassumed their former ascendency, and at the Congress of Vienna (1816) arranged anew the map of Europe. This arrangement suffered during the next fifty years but few changes, the most important of which was the establishment of the new kingdoms of Greece (1821) and Belgium (1830). In 1848 a new revolution made France again a republic, and called forth in Germany, Austria, and Italy a powerful agitation for a radical reconstruction of these countries. The French republic soon gave way to the empire of Napoleon III., who believed it in his interest to encourage the aspirations of the suppressed and dismembered nationalities for a reconstruction of their national unity. The struggles and conflicts arising out of the nationality question are one of the prominent features of the history of Europe since 1851. (The great conflicts which are described in the following lines are illustrated by the Map of the Languages of Europe.) The first great success was won by the Italians, who by the Congress of Vienna had been placed under nine different governments, and who at once organized a movement for the establishment of a united Italy. Until 1848 the Austrian bayonets kept this movement at bay; a temporary success in 1848 ended simultaneously with the downfall of the French republic; but in 1859 the king of Sardinia, who had made himself the banner-bearer of the union party, snatched, with the aid of France, Lombardy from Austria, and annexed the duchies of Central Italy and two-thirds of the Papal territory, to which in the next year the kingdom of the Two Sicilies was added. The new kingdom of Italy in 1866 joined Prussia in her war against Austria, and received as a reward the kingdom of Venetia. Thus the bulk of the Italian nationality became one state, to which in 1870 the remainder of the Papal territory was added as soon as the French patronage ceased, and which is now generally recognized as one of the great powers of Europe.

The agitation of the German people for the reconstruction of a united Germany was chiefly retarded by the rivalry of Austria and Prussia, which in 1866 led to a short but most decisive war between these two countries; in consequence of which Austria had to surrender the leadership in German affairs to Prussia, which organized the North German Confederation, and annexed Hanover, Hesse, Nassau, and Frankfort to its own dominions. The real question at issue in the memorable war of 1870 between France and Germany was whether Germany was strong enough to effect, or France strong enough to prevent, the progress of Germany to a complete reconstruction of the German empire. The overwhelming success of the Germans, which crushed Napoleon, reannexed the lost Reichsland, Elsass-Lothringen, and reestablished their empire, was the second grand triumph of the nationality principle. In other parts of Europe many of the nationalities which are subject to foreign rule are still struggling to establish their independence. The Poles are undismayed by their want of success during the last century, and while they are unable to make headway in Prussia and Russia, they have obtained considerable concessions to their nationality from the weak government of Austria. The Czechs of Bohemia and Moravia, the Slovacks of South-western Austria, the Croatians and Servians in Southern Austria and North-western Turkey, the Rumanians in South-eastern Austria and North-eastern Turkey, the Bulgarians in Turkey, are all dreaming of achieving the establishment of either independent kingdoms of their own nationalities, or at least a separate administration of their affairs on a strictly national basis. The final issue of these national aspirations will decide the ultimate fate of Austria and Turkey. A large portion of the Germans of Austria are looking forward to a reunion with Germany, and among the Slavic tribes of Austria and Turkey the Panslavic movement, which aims at a close confederation of all the Slavic countries under the protectorate of Russia, is gaining strength to an alarming extent. Turkey, in particular, is threatened by the increasing power of the Slavi. It was only the intervention of England and France which, in the Crimean war, prevented Russia from solving the Eastern question according to her own plans; but the early downfall of the Turkish rule is regarded as inevitable by nearly all prominent European statesmen. While the attention of Eastern Europe is almost wholly absorbed by the nationality question, Western Europe is considerably agitated by the struggle between the republican and monarchical forms of government. The crushing defeat of Louis Napoleon, as was to be expected, was followed by a revolution in Paris and the proclamation of the republic, which successfully suppressed a civil war begun by the Paris Commune, and which under the administration of Thiers maintained itself for two years, until in May, 1873, the majority of the National Assembly accepted the resignation of Thiers and elected as president Marshal McMahon, who was expected to co-operate with the majority of the National Assembly in restoring a monarchical rule. In Feb., 1873, the example of France was imitated by Spain, where, after the voluntary abdication of King Amadeus, the majority of the Cortes proclaimed the republic. At the first election of a Constituent Assembly in May, 1873, an overwhelming majority of the electoral districts chose deputies favorable to the establishment of a federal republic. Different from the republicans as a party is the Internationale, a socialistic organization founded in 1867, which aims not only at overthrowing all the monarchies of Europe, but also at destroying the Christian religion, and at a radical change of the present relation between labor and capital. The Internationale already has its representatives in most of the legislative assemblies of Europe, and constitutes an element in European society which can no longer be overlooked. In addition to these conflicts of nationalities, forms of government, and systems of society, the relation between Church and State occupies a large share of the attention of every European legislature. The system of state-churchism, which at the beginning of the century existed in every European state, has been greatly modified. The state governments are loosening their hold of the government of the churches, and conceding to them a higher degree of self-control; and even the principle of a complete separation of Church and State has made considerable progress. The proclamation of papal infallibility by the Vatican Council in 1870 has added new fuel to the conflicts already existing between the Roman Catholic Church and a number of state governments. (See HOFFMANN, "Europa und seine Bewohner," 1835–40, 8 vols.; SCHUBERT, "Handbuch der allgemeinen Staatskunde von Europa," 1835–48, 7 vols.; BRACHELLI, "Die Staaten Europa's," 2d ed. 1864.)

A. J. SCHEM.

Euro'tas [Gr. Εὐρώτας], the ancient name of a river of Greece (in Laconia), now called *Vasilee* or *Vasiliko*. The city of Sparta was situated on this river, which flows through beautiful scenery into the Gulf of Kolokythia (anc. *Laconicus Sinus*).

Euryd'ice [Gr. Εὐρυδίκη], the wife of Orpheus, died in consequence of the sting of a serpent. According to the poetic legend, Orpheus descended to the infernal regions, and persuaded Pluto to restore her to him on condition that she should walk behind Orpheus, and that he should not look back until they had reached the upper world. But he was tempted to look back, and finally lost her. (See VIRGIL, "Georgics," book iv. 454.)

Eusebius, bishop of Emesa, was born near Edessa about 300 A. D. He declined the bishopric of Alexandria, which was offered to him when Athanasius was deposed in the year 341, but he afterwards accepted that of Emesa. He appears to have held the principles called Semi-Arian, and to have been distinguished for his moderation and aversion to controversy. He died at Antioch in 360 A. D., leaving many eloquent homilies, some of which are extant.

Euse'bius [Gr. Εὐσέβιος] OF NICOMEDIA, an ambitious Arian prelate, was a member of the Council of Nice in 325 A. D., having previously become bishop of Nicomedia. He was banished because he defended Arius in this council, but was soon restored to his bishopric, and gained great influence at court. After the death of Arius, Eusebius was the head of the Arian party, who were often called Eusebians. In 339 A. D. he became patriarch of Constantinople. Died in 342 A. D.

Euse'bius Pam'phili, bishop of Cæsarea, an eminent theologian and writer of ecclesiastical history, was born in Palestine about 265 A. D. He assumed the surname PAMPHILI in honor of his friend Pamphilus the martyr. He became bishop of Cæsarea in 314 or 315 A. D., and took a prominent part in the Council of Nice

(325 A. D.). The emperor Constantine the Great, who was his friend, selected him to open this council by an oration. Eusebius was inclined to moderation and peace, used his influence to reinstate Arius, and was a leader of the Semi-Arians. He was one of the bishops who censured Athanasius at the Council of Tyre (334). He was very eminent for learning, as well as for talents. He wrote in Greek, besides several works that are lost, an "Ecclesiastical History from the Christian Era to 324 A. D.," which is of great value, a "Life of Constantine the Great," "Gospel Preparation" ("Præparatio Evangelica"), a "Universal History or Chronicle," and a work "On the Proof or Demonstration of the Gospel" ("De Demonstratione Evangelica"). Died about 340 A. D. Complete editions of his works have been published by Migne in his Patrologia Græca (6 vols., 1856–57), and by Dindorf (1865, *seq.*). A new critical edition of his historical works has been published by Heinichen (1868, *seq.*). (See Baur, "Die Epochen der Kirchlichen Geschichtschreibung," 1852.)

Eusta'chian Tube [named in honor of *Eustachius*, its discoverer], in anatomy, a canal leading from the middle ear to the pharynx. In man the Eustachian tube is nearly two inches long. Beginning at the ear, its first half inch is formed by a passage in the temporal bone, between the petrous and the squamous portions. The fishes have no true Eustachian tube, though some of them have a homologous passage from the ear to the air-bladder; but it exists in the true reptiles, in birds, and in mammals. Its use is probably to enable the hearer unconsciously to increase or diminish the tension of the air within the tympanum, and thus to increase or decrease the sensitiveness to sounds. Closure of the tube impairs the hearing. This organ is sometimes the seat of disease, which may be reached by the catheter, the syringe, and other instruments. Its surgical treatment requires great skill.

Eusta'chius [It. *Eustachio* or *Eustachi*], (Bartholomæus), an eminent Italian anatomist, born at San Severino in the March of Ancona, studied medicine in Rome. The events of his life are mostly unknown. He was a professor in the College della Sapienza, Rome, 1562. He made important discoveries in anatomy, among which was the Eustachian tube, and was the first anatomist who illustrated his works with good engravings on copper. His anatomical plates were engraved in 1552, but were lost for a long time, and were not published until 1714. He wrote a work "On the Controversies of Anatomists" ("De Anatomicorum Controversiis"), which is not extant. He published "Opuscula Anatomica" (1563). He died in poverty in 1574. (See G. C. Gentili, "Elogio di B. Eustachio," 1837.)

Eusta'thius, one of the Church Fathers of the fourth century, is well known on account of his firm adherence to the canons of Nicæa. He was banished in 331 because he would not associate with some anti-Nicæans who had been recalled from exile, and Meletius, then bishop of Sebaste, was appointed in his place. But his adherents did not recognize Meletius, and formed the separate party of the Eustathians. Died about 360.

Eustathius, a monk in Pontus, and after 355 bishop of Sebaste in Armenia, introduced monachism into Pontus. He went so far in his ideas of asceticism as to be condemned by the synod of Gangra in Paphlagonia, because he completely rejected marriage. His followers (the Eustathians) rejected holy ceremonies if performed by married priests, persuaded women to leave their husbands, and are said to have fasted on the Sabbath, which was condemned as heretical.

Eustathius, a celebrated Greek commentator on Homer, was first deacon and then teacher of rhetoric in Constantinople, and after 1155 archbishop of Thessalonica, where he died in 1198. His chief work, a commentary on Homer (7 vols., Rome, 1542–50; 3 vols., Bâle, 1559–60; 4 vols., Leipzic, 1825–30), is considered a rich source of philological learning. Of his commentary on the odes of Pindar only the Proœmium has been preserved.

Eus'tis (Abraham), born at Boston, Mass., Mar. 28, 1786, graduated at Harvard in 1804, was called to the bar in 1807, entered the army as captain of artillery in 1808, served with distinction in the war of 1812–15, received in 1834 a brevet of brigadier-general, and in the same year became colonel of the First Artillery. Died June 27, 1843.

Eustis (George), LL.D., born at Boston, Mass., Oct. 20, 1796, graduated at Harvard in 1815, was private secretary to his uncle, Gov. William Eustis, when the latter was minister at The Hague, removed to New Orleans in 1817, admitted to the bar in 1822, where he took a prominent part in public affairs, and was for some years chief justice of the State supreme court. He was profoundly versed in the civil law. Died Dec. 23, 1858.

Eustis (Henry Lawrence), an American officer and engineer, born Feb. 1, 1819, at Fort Independence, Mass., studied at Harvard, and graduated at West Point in 1842, served as lieutenant of engineers in the construction of fortifications, etc., and assistant professor at the Military Academy till he resigned Nov. 30, 1849, to become professor of engineering in Lawrence Scientific School of Harvard University, Mass. In the civil war he was colonel of the Tenth Massachusetts Volunteers, serving at Williamsport, Fredericksburg, Marye Heights, Salem, Gettysburg, Rappahannock Station, Mine Run, Wilderness, Spottsylvania, Cold Harbor, and many minor actions; and became brigadier-general of volunteers in 1863, but resigned June 27, 1864, to resume his professorship at Cambridge, Mass.

George W. Cullum, *U. S. Army.*

Eustis (William), LL.D., a physician, born in Cambridge, Mass., June 10, 1753. He served as a surgeon in the war of Independence, after which he practised medicine in Boston, and was a member of Congress (1800–05 and 1820–23). He was secretary of war from 1809 to 1812, and was sent as minister to Holland in 1814. In 1823 he was elected governor of Massachusetts. Died Feb. 6, 1825.

Eu'taw, a township and post village, capital of Greene co., Ala., on the Alabama and Chattanooga R. R., 35 miles S. W. of Tuscaloosa. It has three churches, two seminaries, and one weekly newspaper. Pop. of township, 1920.

W. O. Monroe, Ed. "Whig and Observer."

Eu'taw Springs, Battle of, was fought in South Carolina, about 60 miles N. W. of Charleston, Sept. 8, 1781. Gen. Greene, having about 2000 men, attacked a British force under Col. Stuart, who was compelled to retreat, and lost about 630, including prisoners. Gen. Greene lost 535, killed, wounded, and missing.

Eutro'pius, or **Flavius Eutropius,** a Latin historian who flourished about 350–375 A. D. The events of his life are mostly unknown, except that he was secretary to the emperor Julian, and accompanied him in his expedition against the Parthians. He wrote an "Epitome of Roman History" from the foundation of Rome to the time of Valens ("Breviarium Rerum Romanarum"), which became very popular, and has been extensively used as a school-book in modern times. His Latinity is pure and his style simple.

Eu'tyches [Gr. Εὐτύχης], the founder of the heretical sect of Eutychians, was superior of a monastery near Constantinople. He was a zealous opponent of the doctrines of the Nestorians, and was charged with teaching that there is in Christ only one nature—that is, the divine. He was condemned by the Council of Constantinople in 448 A. D., but this decision was reversed by the Council of Ephesus in 449. This triumph was obtained by the violent and disorderly acts of the soldiery and monks. The doctrines of Eutyches were again condemned as heretical by the general Council of Chalcedon in 451 A. D. He was then above seventy years of age. The Eutychians were often called *Monophysites*. (See Monophysites and Jacobites.)

Euxine Sea. See Black Sea.

Evag'oras [Gr. Εὐαγόρας], king of Salamis in Cyprus, was descended from Teucer, a famous hero. He began to reign in 410 B. C., and as an ally of the Athenians and Egyptians waged a long war against the king of Persia, who invaded Cyprus. He was assassinated in 374 B. C., and was succeeded by his son Nicocles.

Eva'grius, a Church historian, born about 536, was at first a lawyer, and defended the patriarch Gregory of Antioch so well that he was appointed city prefect by the emperor Mauricius. He continued the Church histories of Socrates and Theodoret in six books from 431–594. His Church history is compiled with great care and impartiality. The best edition was published by Reading (Cambridge, 1720).

Evangelical Alliance. This is a voluntary association of evangelical Christians from different churches and countries for the purpose of promoting religious liberty, Christian union, and co-operation in every good work. It owes its origin to a widespread and growing desire for a closer union among Protestants, both for its own sake and for a more successful conflict with infidelity on the one hand and superstition on the other. Its object is not to create a union, but to acknowledge, exhibit, and strengthen that spiritual union which has always existed among true Christians as members of Christ's body, but which is sadly marred and obstructed by the many divisions and rivalries of Protestant denominations and sects. It aims not at an organic union, nor at a confederation of churches as such, but simply at a free Christian union of individual members from different churches who hold essentially the same faith; although such a union will naturally tend to bring gradually the churches themselves into closer fellowship and mutual recognition. It claims no official and legis-

lative authority that might in any way interfere with the internal affairs of the denominational organizations or the loyalty of its members to their particular communion. It relies solely on the moral power of truth and love. After a number of preparatory meetings and conferences, the Alliance was founded in a remarkable and enthusiastic meeting held in Freemasons' Hall in London Aug. 19–23, 1846, composed of some eight hundred Christians—Episcopalians, Presbyterians, Independents, Methodists, Baptists, Lutherans, Reformed, Moravians, and others, and including many of the most distinguished divines, preachers, and philanthropists from England, Scotland, Ireland, Germany, France, Switzerland, the U. S., and other countries. Sir Culling Eardly, Bart., presided and became the first president of the British branch. Eloquent addresses were delivered, fervent prayers offered, and nine doctrinal articles adopted; not, however, as a binding creed or confession, but simply as an expression of the essential consensus of evangelical Christians whom it seemed desirable to embrace in the Alliance. These articles are as follows:

"1. The divine inspiration, authority, and sufficiency of the Holy Scriptures.

"2. The right and duty of private judgment in the interpretation of the Holy Scriptures.

"3. The Unity of the Godhead, and the Trinity of the Persons therein.

"4. The utter depravity of human nature in consequence of the Fall.

"5. The incarnation of the Son of God, his work of atonement for the sins of mankind, and his mediatorial intercession and reign.

"6. The justification of the sinner by faith alone.

"7. The work of the Holy Spirit in the conversion and sanctification of the sinner.

"8. The immortality of the soul, the resurrection of the body, the judgment of the world by our Lord Jesus Christ, with the eternal blessedness of the righteous and the eternal punishment of the wicked.

"9. The divine institution of the Christian ministry, and the obligation and perpetuity of the ordinances of Baptism and the Lord's Supper."

Some regard this doctrinal statement as too liberal, others as too narrow (especially on account of Art. 9, which excludes the Quakers, and Art. 8, which excludes the Universalists), while still others would have preferred no creed, or only the Apostles' Creed, the simplest and most generally accepted of all creeds. Nevertheless, it has answered a good purpose, and maintained the positive evangelical character of the Alliance. The American branch, at its organization (1867), adopted the nine London articles, with the following important explanatory and qualifying preamble:

"*Resolved*, That in forming an Evangelical Alliance for the U. S. in co-operative union with other branches of the Alliance, we have no intention to give rise to a new denomination; or to effect an amalgamation of churches, except in the way of facilitating personal Christian intercourse and a mutual good understanding; or to interfere in any way whatever with the internal affairs of the various denominations; but simply to bring individual Christians into closer fellowship and co-operation, on the basis of the spiritual union which already exists in the vital relation of Christ to the members of his body in all ages and countries.

"*Resolved*, That in the same spirit we propose no new creed; but, taking broad, historical, and evangelical catholic ground, we solemnly reaffirm and profess our faith in all the doctrines of the inspired word of God, and in the *consensus* of doctrines as held by all true Christians from the beginning. And we do more especially affirm our belief in the *divine-human person and atoning work of our Lord and Saviour Jesus Christ*, as the only and sufficient source of salvation, as the heart and soul of Christianity, and as the centre of all true Christian union and fellowship.

"*Resolved*, That, with this explanation, and in the spirit of a just Christian liberality in regard to the minor differences of theological schools and religious denominations, we also adopt, as a summary of the *consensus* of the various Evangelical Confessions of Faith, the Articles and Explanatory Statement set forth and agreed on by the Evangelical Alliance at its formation in London, 1846, and approved by the separate European organizations; which articles are as follows," etc.

The Evangelical Alliance thus auspiciously organized soon spread throughout the Protestant world. Branch Alliances were formed in Great Britain, Germany, France, Switzerland, Sweden, and even among the missionaries in Turkey and East India; quite recently also in Australia, in Brazil, and among the Protestant missionaries in Japan (Dec., 1873). There is no central organization with any controlling authority, and the General Alliance appears in active operation only from time to time when it meets in general conference, which has assumed the character of a Protestant œcumenical council, but differs from the œcumenical councils of the Greek and Roman churches in claiming only moral and spiritual power. The various national branches are related to each other as members of a confederation with equal rights. The British branch, being the oldest and largest, and having the most complete organization, with a house (in London, No. 7 Adam street, Strand) and regular officers who devote their whole time to it, has been heretofore the most influential; the continental branches are more elastic, and confine themselves to occasional work; the American branch, which was organized at the Bible House, New York, in 1867 (a previous attempt having failed on account of the anti-slavery agitation before the civil war), has in a short time become the most vigorous and popular; for in the U. S., where all Christian sects are represented on a basis of equality before the law, there is also the greatest appreciation of religious freedom, the strongest desire for Christian union and co-operation, and the widest field for the realization of the idea of a universal Christian brotherhood on the basis of a free development of denominational peculiarities in dogma, discipline, and worship. We now give a brief summary of the history and results of the Alliance.

1. As regards the promotion and defence of *religious liberty* wherever assailed. The Alliance assumed from the beginning that freedom of conscience and Christian union, far from being inconsistent with each other, are one and inseparable; that freedom is the basis of union, and union the result and support of freedom; that a union without freedom is only a dead mechanical uniformity; that true union implies variety and distinction, and a full recognition of the rights and peculiar gifts and mission of other members and branches of Christ's kingdom. The Roman Church maintains union at the expense of freedom, and, while advocating liberty of conscience for herself, denies it to all others in principle, and, where she has the power, in practice also. Since the formation of the Alliance many cases of persecution more or less severe have occurred, especially in Southern Europe, under the operation of penal laws against religious dissenters; and the united efforts of the different branches of the Alliance, through the press and by deputations, have had a considerable moral influence in bringing about those remarkable changes in favor of religious liberty which have taken place among the Latin races and in Turkey within the last twenty years. The Alliance has successfully exerted its influence for the release of the Madiai family in Tuscany, and of Matamoros, Carrasco, and their friends who, during the reign of Queen Isabella in Spain, were thrown into prison and condemned to the galleys for the sole crime of reading the Bible and holding private meetings for devotion. It aided in inducing the sultan of Turkey to abolish the death-penalty for apostasy from Mohammedanism in his dominions. It interceded for the Methodists and Baptists in Sweden, which has since abrogated the penal laws against Roman Catholics and Protestants not belonging to the Lutheran Confession. It sent in 1871 a large deputation, in which prominent citizens of the U. S. took the leading part, to the czar of Russia to plead for the oppressed Lutherans in the Baltic Provinces, and these have not been disturbed since that time. It sent a similar deputation to the embassy from Japan, when they visited this country and the courts of Europe in 1872, to remonstrate against the persecution of Christians, mostly Roman Catholics, in that distant empire of the East, and the persecution has since ceased. It has not forgotten the Nestorians in Persia, who appealed to the Alliance for protection against the oppression of a Mohammedan government; and just now (1874) it prepared a memorial to the czar on the persecution of Baptists in the south of Russia. The force of public opinion on the subject of freedom of conscience and religious worship, as expressed by the Alliance, has always found a respectful hearing, and must sooner or later be obeyed by every civilized government on the globe.

2. As regards the cause of *Christian union*, which is the other great object of the Alliance, it is promoted mainly by means of general conferences of an international and interdenominational character, which are arranged from time to time in different capitals by the branch in whose bounds it meets, with the co-operation of the sister branches. These meetings last several days, and are spent in prayer and praise, brotherly communion, and discussions of the most important religious questions of the age. Six general conferences have been held so far. The first general conference took place in London in 1851, the year of the great exhibition of the works of industry of all nations in the British metropolis; the second in Paris, 1855; the third in Berlin, 1857; the

fourth in Geneva, 1861; the fifth in Amsterdam, 1867; the sixth in New York, 1873. Rome is spoken of as the place for the next conference. These meetings were all well attended, and left a most favorable impression upon the delegates and the country in which they were held. But the most popular, enthusiastic, and effective of all was the one held in New York, Oct. 2–12, 1873, which from the beginning to the close was a most complete success, surpassing every expectation. For the first time in history, American, European, and Asiatic Christianity met face to face in the New World, and took counsel together on the state of Christendom, on Christian union, Christian life, Christianity and infidelity, Christianity and superstition, Christianity and civil government, Christian missions at home and abroad, Christian philanthropy and reform of social evils. The religious community of our commercial metropolis took the deepest interest, and thronged the meetings by thousands in the several churches and public halls from morning till night, and the secular and religious press, without exception, spread the reports among millions of readers. The foreign delegates were deeply impressed with the life and energy of American Christianity and American institutions, and spread their new convictions all over the Old World. "It is quite impossible," writes Charles Reed, an influential member of the British Parliament, and one of the delegates (in one of the British periodicals), "to describe the course of these meetings in New York, much less the spirit in which they were conducted. The numbers of delegates from all parts of Europe and Asia, the attendance daily for ten days of thousands of persons, the subjects of discussion, are evidence of the success of the gathering, while the full reports by the daily press and the attention paid by public bodies showed that the influence spread far and wide among the population of the city. . . . It was occasionally felt that such a conference could not have been held elsewhere than in New York. . . . No words can convey the sense I have of the importance of this conference, as inaugurating a new era in the history of Christian union." The same testimony, in even more enthusiastic language, came back after the return of the delegates from every part of Europe, and the effect of the conference in encouraging faith and Christian work and cementing the bond of union, especially between Great Britain and America, cannot be estimated. For a full report of the addresses and proceedings see the stately volume, "History, Essays, Orations, and other Documents of the Sixth General Conference of the Evangelical Alliance held in New York," edited by Schaff and Prime, and published by the Harpers, New York, 1874 (pp. 773). The proceedings of the previous meetings were published by the British branch in English, and also in German, Dutch, and French by the continental branches. The American branch has issued ten documents of minor importance from its office in the Bible House, New York. Biennial meetings are hereafter to be held in the U. S. for the discussion of topics of general interest to the religious community in America.

PHILIP SCHAFF.

Evangel'ical Associa'tion, popularly but incorrectly known as the **German Methodist Church,** a body of American Christians, chiefly of German descent, organised by the Rev. Jacob Albright, a native of Eastern Pennsylvania. Regarding the doctrines and morals that prevailed in the German churches of that part of Pennsylvania as corrupt, Albright undertook about 1790 a work of reform among them. At a meeting of his converts in 1800, called for the purpose of deliberating on the measures best suited for advancing the new religious movement, Albright was unanimously elected pastor or bishop, and authorized to exercise all the functions of the ministerial office over the members of the organization. In the course of time annual conferences were established, and in 1816 the first general conference was held in Union co., Pa., consisting of all the elders in the ministry. Since 1843 the general conference, consisting of delegates from the annual conferences, has regularly met once every fourth year. During the first thirty years of its existence the Evangelical Association met with violent opposition, but since then it has quietly and rapidly advanced. As the church repeatedly took action on the slavery question and sided with the anti-slavery churches, its progress was wholly within the boundaries of the Northern States, and even in 1873 no conference had been established in the Southern States. In 1863 there was one in Canada and one in Germany.

In doctrine and theology the Evangelical Association is Arminian; with regard to sanctification, Wesleyan; in the form of government and mode of worship it generally agrees with the Methodist Episcopal Church (of which Albright, prior to beginning his reformatory labors in the German churches, was a member). The ministers, who, like the Methodists, practice itineracy, are divided into deacons and elders; the bishops and presiding elders are elected for a term of only four years—the former by the general conference, the latter by the individual conferences. The general conference is the highest legislative and judicial authority in the Church; the transactions of the annual and quarterly conferences are mostly of an executive and practical nature. A charitable society for the support of the widows and orphans of poor itinerant preachers was established in 1835, and a missionary society in 1838. There is moreover a Sunday school and tract society, and church-building societies have been established in several conferences. A denominational publishing-house at Cleveland, O., publishes six periodicals—three in German and three in English; besides, two periodicals are published in Germany. The literary institutions of the Church in 1872 were—the North-western College, in Naperville, Ill.; the Union Seminary, in New Berlin, Pa.; the Blairstown Seminary, in Blairstown, Ia.; and the Ebenezer Orphan Institution, at Flat Rock, O. In 1871 the Church had fifteen annual conferences, inclusive of those of Canada and Germany, 587 itinerant and 401 local preachers; 905 churches; 1033 Sunday-schools, with 56,028 scholars and 11,646 officers and teachers; and 72,979 members. A history of the Association has been begun by W. W. Orwig.

Evangel'ical Church Con'ference, the name applied to periodical meetings of the Protestant state churches of Germany. The idea of these meetings originated with King William of Würtemberg in 1815. The first conference, held at Berlin in 1846, had representatives from almost every German state. At the second conference, held in 1852 at Eisenach, an official central organ was established at Stuttgart ("Allgemeine Kirchenblatt für das evangel. Deutschland"). The conferences from 1855 to 1868 were all held at Eisenach.

Evangel'ical Chur'ches are those bodies of Christians which believe in the divinity of Christ, in the necessity of his atonement, and in personal repentance and faith as essential to salvation.

"Evangelische Kirche" ("Evangelical Church") is the official title of the Established Church of Prussia, formed in 1817 by the union of the Lutheran and the Reformed churches. The Lutherans and Reformed (Calvinistic) churches of Baden, Würtemberg, and other German states have been similarly united.

The "evangelical party" in the Church of England is that section of the Church which professes to attach especial importance to the teachings of the New Testament, and which is charged with neglecting or slighting church authority and underrating the efficacy of the sacraments.

Evangel'ical Coun'sels [Lat. *consilia evangelica*] are such directions or admonitions in the Roman Catholic Church as are not in themselves obligatory upon any one, but are recommended by the Church to some persons as highly advantageous to spiritual excellence. The chief evangelical counsels are voluntary virginity, poverty, and obedience to monastic rules. Some writers reckon as evangelical counsels the scriptural recommendation to turn the left cheek to the man who has struck one's right cheek, to go two miles with a person who desires one's company for one mile, etc. There are reckoned twelve of these counsels.

Evangel'ical U'nion, a body of Scotch Independents, called **Morisonians,** from Rev. James Morison, their original leader. In 1843 they left the United Secession Church. They have been joined by some Congregational churches of Scotland and England. They reject a part of the Calvinistic doctrines, and have a theological school at Glasgow.

Evan'geline, a twp. of Charlevoix co., Mich. Pop. 90.

E'vans, a post-village, capital of Weld co., Col., 47 miles N. by E. of Denver, where the Denver Pacific R. R. crosses South Platte River and also the Golden and Julesburg R. R. It has one bank, three hotels, two churches, a court-house, a large flouring-mill, and one newspaper. It is the centre of the St. Louis Western colony. It has a thriving trade, good water-power, and ample means for irrigating the excellent lands which surround the town. Pop. 189.

A. C. TODD, ED. "EVANS JOURNAL."

Evans, a township of Marshall co., Ill. Pop. 1989.

Evans, a twp. and post-village of Erie co., N. Y. The township lies on Lake Erie, and contains a number of villages. Pop. of Evans Centre, 150; of township, 2593.

Evans (AUGUSTA J.; since 1868 Mrs. L. M. WILSON), born near Columbus, Ga., in 1836, removed in childhood, with her father, to Texas, and in 1849 removed to Mobile. She has published "Inez, a Tale of the Alamo," "Beulah" (1859), "Macaria" (1864), "St. Elmo" (1866), "Vashti" (1869). She is a novelist of great talent.

Evans (Sir DE LACY), D. C. L., a British general, born at Moig, in Ireland, in 1787. He served at the battles of Baltimore (1814), New Orleans (1815), and Waterloo (1815). He was a Liberal member of Parliament from 1831 to 1841.

In 1835 he was appointed commander of a legion of 10,000 men raised in Great Britain to fight for the queen of Spain. He defeated the Carlists at several places in 1836 and 1837. In 1846 he was returned to Parliament for Westminster, which he represented for many years. Having been raised to the rank of lieutenant-general, he commanded a division at the battle of the Alma and at Sebastopol, in Oct., 1854. Died Jan. 9, 1870.

Evans (Ellicott), LL.D., was born at Batavia, Genesee co., N. Y., June 19, 1819, and was educated at Harvard. In 1860 he became professor of law and political economy at Hamilton College, Clinton, N. Y.

Evans (Frederick William), born at Leominster, England, June 9, 1808, came in 1820 to the U. S. with his father. He was apprenticed to a hatter, and occupied his leisure hours with study. He became in theory a socialist, and studied the works of Owen, Fourier, and other leaders in the various projects for social reform. He visited England, and after his return went to visit the communities of United Shakers at Mount Lebanon, N. Y., for the purpose of studying their system, to which he became a convert. He afterwards became the presiding elder brother of the communities of that place and the leader of the sect in the U. S. His teachings have added new dogmas and considerably modified the old doctrines of Shakerism. He is known as a public lecturer, a contributor to periodical literature, and author of an "Autobiography," "Anne Lee," "Religious Communism," and other works.

Evans (George), born at Hallowell, Me., Jan. 12, 1797, graduated at Bowdoin in 1815, called to the bar in 1818, was a member of Congress from Maine (1829–41), U. S. Senator (1841–47), and held various important offices in his native State. Died April 5, 1867.

Evans (Hugh Davy), LL.D., born at Baltimore, Md., in 1792, was a prominent jurist and strong friend of the Protestant Episcopal Church. He wrote an "Essay on Pleading" (1827), "Maryland Common-Law Practice" (1839), and "Essays" upon various Church questions (1844, 1851, 1855, etc.). Died July 16, 1868.

Evans (John), M. D., geologist, was born at Portsmouth, N. H., Feb. 14, 1812, graduated at the St. Louis Medical College, served on several State and Territorial geological surveys under Dr. D. D. Owen, and discovered remarkable fossil deposits in the Bad Lands of Nebraska. He afterwards performed the U. S. geological survey of Oregon and Washington Territory. Died April 13, 1861.

Evans (Marian C.). See Lewes (Marian E.).

Evans (Oliver), an American inventor, born in 1755 at Newport, Del. Died in New York April 25, 1819. His most valuable inventions were the automatic flour-mill and the high-pressure steam-engine. Before his time grain and flour were moved in the mill by manual labor. His improvements, which effected a complete revolution in the manufacture of flour, consisted of the elevator, the conveyer, the hopper-boy, the drill, and the descender. By means of this machinery grain was conveyed from a wagon or a boat into the mill, then cleaned, ground, bolted, and delivered into barrels without the intervention of human hands. After great opposition these improvements were introduced into the celebrated Ellicott Mills, near Baltimore, where 325 barrels of flour were daily made. The saving there effected by Evans's contrivances was estimated at more than fifty cents per barrel. As the production of wheat alone in the U. S. in 1870 exceeded 287,000,000 bushels, the benefits arising from the use of the automatic flour-mill are not likely to be over-estimated.

In 1772, while yet an apprentice, Evans endeavored to discover some substitute for animal power in moving wagons; fortunately, an incident, related by his brother, gave the right direction to his investigations. In a blacksmith shop near by about a gill of water was poured into a gun-barrel, after stopping up its touch-hole; then a tight wad was rammed into the barrel, and it was placed in the smith's fire; "presently the barrel discharged itself with a loud crack, as if it had been loaded with powder." It instantly occurred to Evans that this was the power he wanted. He subsequently found a book containing a description of the atmospheric steam-pump used at the English coal-mines, and was astonished to find that steam was solely employed for obtaining a vacuum by its condensation, thus allowing only the pressure of the atmosphere to move the piston. He made experiments in which the pressure of steam moved the piston, and in 1781 announced that he could propel boats and wagons by means of steam. No attempt was made to introduce this invention until after the close of the Revolutionary war. In 1786 the State of Pennsylvania gave him the exclusive right to use in that State his flour-mill, but refused to grant the same right to use his steam-wagon. In 1787, however, Maryland granted him the right to use both inventions in that State. In order to obtain assistance in building his road-engine, he exhibited his drawings and plans to capitalists and engineers; failing to find one who would join him in the enterprise, he twice sent his plan and specifications to England, in the vain hope of convincing foreign engineers of the feasibility of his device. Finally, in 1801 he decided to devote all his earnings from his other inventions, about $3700, to the construction of a stationary steam-engine on the direct-pressure plan. It was completed and put into operation in the city of Philadelphia, and continued to be used successfully for many years in sawing marble and grinding gypsum. Thus, 1801 marks a new era—the introduction of the most important of all engines. Soon after, by order of the board of health of Philadelphia, Evans constructed a device for cleaning or dredging docks. It consisted of a small scow or flatboat, with a small steam-engine of five-horse power and boiler on board to work the dredging machinery. In order to show its adaptability to locomotion, he connected his engine, by means of pulleys and bands, with four wooden wheels turning on wooden axles beneath the boat, also with a paddle-wheel behind it. This singular contrivance for moving on land and water he called the "Eructor amphibolis." By steam alone it was driven over the highway from his workshop to the Schuylkill River, about one mile and a half, where it was launched, and from thence propelled down the Schuylkill to its mouth, and up the Delaware River to the city, a distance of fourteen or fifteen miles. This was the first application of the high-pressure principle to locomotion, and the Evans engine, with important improvements made since his day, drives all the locomotives and steam-carriages now in use. Evans also invented the cylinder boiler, with a cylindrical internal flue, commonly known as the "Cornish boiler."

Three varieties of steam-engines are now in use—namely, the condensing or low-pressure engine, the non-condensing or high-pressure engine, and a combination of these two, called the compound engine. In the condensing and the compound engines power is derived from heat, which converts water into steam; also from cold, which reconverts steam into water. These engines are only available where the large quantity of cold water required for condensing steam can be readily obtained. No such condition attends the use of the Evans non-condensing engine, in which the direct action of high-pressure steam on a relatively small piston moving with great velocity gives the required power. Compared with the other two, it is small, of simple construction, cheap, always available, and therefore of almost universal application. Experience warrants the assertion that the high-pressure steam-engine is the most valuable prime mover ever devised. A great invention when brought into practical operation is an important element in human progress, for its power outlasts its originator and increases with time. It is a continual source of wealth, because labor saved is, virtually, labor gained. The devices of Oliver Evans were of this stamp, and have won for him a high place among the benefactors of our race.

Samuel D. Tillman.

Evans (Robley D.), U. S. N., born Aug. 18, 1844, in Floyd co., Va., entered the navy as a midshipman Sept. 20, 1860, became an ensign in 1863, a lieutenant in 1866, a lieutenant-commander in 1868, served in both attacks upon Fort Fisher, N. C., and in the attempt to storm the fort was four times wounded. Foxhall A. Parker, U. S. N.

Ev'ansburg, a post-village of Sadsbury township, Crawford co., Pa. Evansburg Station (Stony Point P. O.) is 2¾ miles S., on the Atlantic and Great Western R. R. The village is on Conneaut Lake, which is 1074 feet above the sea. Pop. 174.

Evans Centre (Evans P. O.), a village of Evans township, Erie co., N. Y., on Big Sister Creek, 1½ miles from Angola, has some manufactures. Pop. 150.

Evans Mills, a post-village of Le Ray township, Jefferson co., N. Y., on the Rome Watertown and Ogdensburg R. R., 11 miles N. N. E. of Watertown. Pop. 500.

Ev'ansport, a post-village of Tiffin township, Defiance co., O. Pop. 191.

Ev'anston, a post-village of Cook co., Ill., on Lake Michigan and the Chicago and North-western R. R. (Milwaukee division), 12 miles N. of Chicago. It is a very handsome suburban town, the seat of the North-western University, a wealthy and flourishing institution, having substantial and costly buildings, extensive libraries, and a museum. It is noted for its pleasant situation, its numerous churches, rapid growth, and social attractions. It has one newspaper, two banks, gas-works, numerous stores, etc. No intoxicating liquors can legally be sold within 4 miles of the university. It is also the seat of Garrett Biblical

Institute. Many of its citizens do business in Chicago. Pop. of township, 3062.

ALFRED L. SEWELL, ED. OF "INDEX."

Evanston, a post-village, county-seat of Uintah co., Wy. Ter., situated on Bear River and on the Union Pacific R. R., 76 miles E. of Ogden, and halfway between Omaha and San Francisco. The railroad machine-shops are here, employing over 100 men; it has also a large steam sawmill, one library, three churches, public school, four hotels, a railroad eating-house, two banks, and thirty business-houses. An abundance of coal is found within three miles, of which over 100 cars are shipped per day. Iron ore is also found. It has one weekly newspaper.

WM. E. WHEELER, PROP. "AGE."

Ev'ansville, a city and port of entry, capital of Vanderburg co., Ind., is on the Ohio River, 185 miles below Louisville and 192 above Cairo. It is the southern terminus of the Wabash and Erie Canal, and of the Evansville and Crawfordsville R. R., which connects it with Terre Haute, 109 miles distant. It is 161 miles E. S. E. of St. Louis by the St. Louis Evansville Henderson and Nashville R. R. Evansville is pleasantly situated on a high bank, has an extensive trade, and is the principal shipping-point of South-western Indiana. It has a fine court-house, a U. S. marine hospital, several public halls, and four national banks; also a number of flour-mills, iron-foundries, machine-shops, and manufactures of wool, leather, etc. Four daily newspapers are issued here. Pop. in 1860, 11,484; in 1870, 21,830.

Evansville, a post-township of Douglas co., Minn. Pop. 250.

Evansville, a post-village of Rock co., Wis., on the Chicago and North-western R. R. (Madison division), 22 miles S. by E. of Madison. It has a national bank, one weekly newspaper, a graded school, seminary, one machine-shop, one steam cabinet-manufactory, grist-mill, five churches, and two hotels. Principal business, farming.

I. A. HOXIE, ED. "REVIEW."

Evapora'tion [from the Lat. *e*, "out," "off," and *vapor*, "steam" or "vapor;" literally, the act of going off as vapor] is the passage of a substance from the liquid or solid state to the condition of vapor, especially applied to such a change when it takes place at a temperature below the boiling-point. It was once taught that the air had a sponge-like power of taking up or dissolving a certain quantity of vapor of water and other liquids, and that this power increased with the temperature; but it is now known that evaporation takes place to the same degree in a vacuum as in the air, and far more rapidly. It has been shown by Dalton that the elastic force of all vapors is the same, whether mixed with gas or air, or not; and that air is never truly saturated with vapor unless it contains an amount sufficient to saturate a vacuum of the same extent.

Heat is the great cause of evaporation; so that the hotter the air becomes the more rapidly is vapor formed. When the air is at rest the space near an evaporating surface becomes loaded with vapor, and the process becomes much slower than when the air is in motion, both by reason of increased tension and of loss of heat; for evaporation is a great absorber of heat. Indeed, the most intense degree of cold with which we are acquainted is caused by the evaporation of volatile liquids, such as ether, rhigoline, etc.; the lowest point yet reported being —220° F., artificially produced by the evaporation in vacuo of a mixture of liquid nitrous oxide (N_2O) and carbon disulphide (CS_2).

Ev'art, a post-village of Osceola co., Mich., situated in the heart of a great lumber country, about midway between the two great lakes. It is a place of two years' growth, and has seven saw and shingle mills, a foundry and machine-shop, two church societies, and one newspaper. Pop. of township, 168. HESS & CHASE, PROPS. "REVIEW."

Ev'arts (JEREMIAH), an American editor, born in Sunderland, Vt., Feb. 3, 1781, graduated at Yale College in 1802. Having studied law, he was admitted to the bar in 1806, and became editor of the "Panoplist," a religious paper of Boston, about 1810. In 1821 he was chosen corresponding secretary of the board of commissioners for foreign missions. Died May 10, 1831. He was a man of rare fineness and force of character.

Evarts (WILLIAM MAXWELL), LL.D., an eminent lawyer, a son of the preceding, was born in Boston, Mass., in Feb. 6, 1818; graduated at Yale College in 1837, and studied law, which he practised with great distinction in the city of New York, where he was admitted to the bar in 1840. He became a Republican soon after that party was organized. He was the leading counsel employed for the defence of President Johnson in his trial before the Senate in April and May, 1868, and was attorney-general of the U. S. from July, 1868, to Mar. 4, 1869. He was one of three lawyers appointed by President Grant in 1871 to defend the interests of citizens of the U. S. before the tribunal of arbitrators who met at Geneva to settle the "Alabama claims." He is one of the most eloquent advocates in the U. S. Several of his public addresses have been published.

Eve, a township of Monroe co., Ark. Pop. 297.

Eve (JOSEPH A., M. D. See APPENDIX.

Eve (PAUL FITZSIMONS), M. D., was born June 27, 1806, near Augusta, Ga., graduated at the University of Georgia in 1826, graduated as M. D. at the University of Pennsylvania in 1828, and studied several years in Europe, was a surgeon in the Polish revolution of 1831, and received the Golden Cross of Honor of Poland in that year, became professor of surgery in the Medical College of Georgia in 1832, in Louisville University (Ky.) in 1849, in Nashville University (Tenn.) in 1850, and in Missouri Medical College, St. Louis, in 1868. In 1870 he became professor of operative and clinical surgery in the University of Nashville. Prof. Eve was president of the American Medical Association in 1857. He served as a surgeon in the Confederate army. He has been editorially connected with professional journalism for many years, and is the author of very numerous monographs upon surgery, etc. Dr. Eve has long held a high position among the surgeons of the U. S. He has crossed the Atlantic fourteen times in the interest of his profession. His youthful service in Poland was voluntary and without pay. In the Medical College of Ga. he delivered eighteen courses of lectures. He has declined professorships in New York City and Philadelphia, and the surgeon-generalship of Tennessee. He has had remarkable success as a lithotomist. Of 92 bilateral operations for stone in the bladder, 8 only terminated fatally; of the last 48 cases, 46 recovered; of 105 applicants for relief, not one was refused.

Evec'tion [from the Lat. *e*, "out," and *veho*, *vectum*, to "carry;" literally, "being carried out" of its proper or natural position], an inequality of the moon's motion, depending on the position of the transverse axis of the moon's orbit, as compared with the earth's radius vector. The eccentricity of the lunar orbit varies with the relative position of these lines. It is maximum when they are coincident, and minimum when they are perpendicular to each other. The variation of the eccentricity affects the equation of the centre, increasing or diminishing correspondingly the moon's mean longitude. This inequality is called evection.

Ev'eline, a township of Charlevoix co., Mich. Pop. 294.

Evening Schools are established in many of the larger towns of Great Britain and Ireland, and in the greater part of the cities of the U. S., for the instruction of artisans and others who have been unable to receive education in childhood. In many instances such schools have been maintained by private benevolence, but of late years they are, at least in the U. S., generally established, and wholly or in part maintained, by local or municipal authorities. Their sphere of usefulness is rapidly extending, and the course of study becomes more and more important. Boston, Mass., has an evening high school, and in our larger cities, as in nearly all the important towns of Massachusetts, industrial and free-hand drawing is taught. The Cooper Union, N. Y., has a flourishing evening school of design. Nearly 22,000 names of pupils were registered in the evening schools of N. Y., for the year 1869-70.

Evening Shades, a post-village, capital of Sharpe co., Ark., about 22 miles N. of Batesville.

Ev'erdingen, van (ALBERT), a painter of landscapes, born in Holland in 1621. His taste was for wild scenery, rocks, torrents, the stormy sea; his pencil was bold, his coloring strong and effective. His etchings are famous. Died in 1675.

Ev'erest, Mount, the highest mountain of the earth, is in the eastern range of the Himalayas, in Northern Nepaul; lat. 27° 59′ N., lon. 86° 54′ E. According to the measurement of Waugh in 1856, the altitude is 29,002.

Ev'erett, a thriving post-township of Middlesex co., Mass. Until 1870 it formed a part of Malden. It is supplied with water from the Spot Pond Works of Malden. It is two miles from Boston, and connected therewith by the Eastern R. R. and the Middlesex horse railroad. It has four churches and excellent schools; also one weekly newspaper. Pop. 2220.

GRAY & METCALF, EDS. AND PUBS. "PIONEER."

Everett, a township of Newaygo co., Mich. Pop. 231.

Everett, a post-township of Cass co., Mo. Pop. 905.

Everett, a township of Burt co., Neb. Pop. 277.

Everett, a post-village of Bedford co., Pa., has one weekly newspaper.

Ev'erett (Alexander Hill), LL.D., an American scholar and diplomatist, born in Boston Mar. 19, 1792, was a brother of Edward Everett, noticed below. He graduated at Harvard in 1806, and studied law in the office of John Q. Adams, with whom he went to Russia as secretary of legation in 1809. Having returned home in 1812, he began to practise law in Boston, and married Lucretia Peabody. He was chargé d'affaires at The Hague for nearly six years (1818–24), and published in 1821 an able work entitled "Europe, or a General Survey of the Principal Powers," etc. In 1825 he was appointed minister to the court of Spain by President Adams. During his residence at Madrid he wrote "America, or a General Survey of the Political Situation of the Several Powers of the Western Continent" (1827). He returned home in 1829, and became editor of the "North American Review," which he conducted for about five years. Having been appointed commissioner to China by President Polk in 1845, he died at Canton June 29, 1847.

Everett (Charles Carroll). See Appendix.

Everett (Edward), LL.D., D. C. L., an orator and statesman, born in Dorchester, Mass., April 11, 1794. He was a son of Rev. Oliver Everett, who died in 1802. He attended a school in Boston, at which Daniel Webster for a short time supplied the place of his brother, Ezekiel Webster, the regular master. He was twice a "Franklin medal scholar" of the Boston public schools, and for a few months a pupil of Exeter Academy. In 1811 he graduated at Harvard University with the highest honors of his class, being then little more than seventeen years of age. In 1812 he was appointed a tutor at Harvard while pursuing theological studies in preparation for the ministry. On Feb. 9, 1814, he was ordained as pastor of the Brattle street (Unitarian) church in Boston, where the fascination of his manner and the power and beauty of his sermons made the deepest impression on his hearers. In Mar., 1815, he accepted the Eliot professorship of Greek literature at Harvard, and terminated his career as a settled clergyman before he was quite twenty-one years of age. Proceeding at once to Europe, he studied for two years at the University of Göttingen, of which he became Ph. D. in 1817, and then travelled extensively in Europe, making special visits to Athens and Constantinople with a view to thorough preparation for the studies of his professorship, upon which he entered soon after his return in 1819. A brilliant course of lectures on ancient Greece and its architecture, with illustrations of the magnificent ruins which he had just visited, inaugurated his accession to the chair, which he held until 1825. His fame as a secular orator—which will probably outlast all his other titles to the remembrance of posterity—may be dated from the delivery of his Phi Beta Kappa oration at Cambridge in Aug., 1824, when the presence of La Fayette inspired him with an eloquence which had never been equalled within the walls of the university, and which won for him a widespread popular celebrity. Succeeded as it was in a few months by his oration at Plymouth on the 22d of December of the same year, an enthusiastic admiration was kindled and kept alive, which could only be satisfied by calling him into political service. A nomination for Representative in Congress soon followed, and Mr. Everett served the district of Middlesex in that capacity from 1825 to 1835, distinguishing himself greatly by unwearied devotion to duty, as well as by elaborate and masterly speeches. In 1836, after ten years of congressional service at Washington, he was called home to be governor of Massachusetts, and was continued in that office, by successive annual elections of the people, until 1840. A single vote, out of more than a hundred thousand, defeated his re-election. Going at once, for a second time, to Europe, he established himself in one of the Medicean villas at Florence, and prepared to enter upon his long-cherished purpose of writing history. "Rome in the time of Cicero" was one among many of the congenial themes which he had meditated. But hardly a year had elapsed before he received a call to proceed without delay to London as minister plenipotentiary of the U. S., and he entered upon that mission in 1841 at a moment when questions of the greatest delicacy were pending between the two nations. Returning home in 1845 after four years of diplomatic service in England, he was met almost at the wharf on landing with an inexorable demand that he should assume the then vacant presidency of the university at Cambridge. Accepting the position reluctantly, he gave three years of anxious and strenuous labor to its duties, and then eagerly laid them down. A brief interval of rest, which he sorely needed and had richly earned, afforded him time to establish himself again in Boston with a choice library around him, and to contemplate afresh some larger literary work than had yet seriously engaged him. But the death of Mr. Webster in Nov., 1852, left a vacancy in the department of state at Washington, which he was immediately summoned to fill; and on the expiration of his brief term as secretary of state, by the termination of President Fillmore's administration in 1853, he was elected by the legislature of Massachusetts a Senator in Congress. He held that place but a single year, when, owing to ill-health, he retired finally, as it proved, from the cares and burdens of official life. In 1860, indeed, he accepted a nomination for the vice-presidency of the U. S., but failed of an election; and the last ten years of his life were thus left undisturbed by political responsibilities. But nothing like private life, as that phrase is commonly understood, awaited his retirement. Calls were soon heard from a hundred sources for the exercise of his personal influence and his oratorical powers in behalf of some charitable institution, or in commemorating some historical event, or in eulogizing some illustrious person. It was not in his nature to decline such calls. During the first half of these last ten years his topics were within the common range of occasional discourses—"Dorchester (his native place) in 1630, 1776, and 1856;" "The Uses of Astronomy;" "The Importance of Agriculture;" "Charitable Institutions and Charity;" "Daniel Webster;" "Thomas Dowse;" "Academical Education;" "The Dedication of the Boston Public Library," of which he was one of the building commissioners, as well as president of the trustees. To this period also belongs his memorable and patriotic pilgrimage in the cause of rescuing Mount Vernon from the danger of falling into the hands of speculators, and securing it as a national possession; during which he delivered his address on "The Character of Washington" in all quarters of the Union, and paid over about $60,000 to the treasurer of the fund as the product of his eloquence. But the remainder of these last ten years of his life was to be mainly devoted to more painful and pressing themes. The opening of the civil war gave a new field to the labors of his pen and of his tongue, and from "The Flag-raising in Chester Square" (Boston), on the 27th of April, 1861, to his last utterance for "The Relief of Savannah," in Faneuil Hall on the 9th of Jan., 1865, just six days before he died, his thoughts, his time, and almost all his numerous addresses, filling nearly 350 pages of an octavo volume, were given to the support of the Union cause. He died in Boston Jan. 15, 1865.

Of such a career the records are happily abundant. His political and congressional speeches and his official papers have, it is true, never been collected, and are to be found only in separate pamphlets or in the columns of newspapers. They would make an interesting and valuable volume. His literary essays, too, must be sought for in the pages of the "North American Review," of which he was for several years editor, and to which he contributed many admirable articles. An attractive and instructive volume of literary miscellanies cannot fail to be forthcoming at no distant day from these materials. His contributions to the "New York Ledger" during the war were collected and published by himself in a volume entitled "The Mount Vernon Papers." So also he published, in an independent volume, his "Biography of Washington," prepared for the "Encyclopædia Britannica" at the request of Lord Macaulay. His "Defence of Christianity," a little work printed as long ago as 1814, is to be found on the shelves of public libraries or among the rarities of bookworms, but it ought never to be omitted from the catalogue of his earliest and most remarkable manifestations. His fame, however, as a scholar, an orator, a philanthropist, and a patriot will mainly rest on the four substantial volumes of his "Orations and Speeches"—two of them published in 1850, the third in 1859, and the fourth (by his sons) in 1868. The exhaustive index to the three first, prepared as a labor of love by Dr. Allibone, affords an easy reference to their rich and curiously diversified contents. They form together a most striking illustration of the times in which he lived, as well as an almost perfect picture, in the choicest mosaic, of the man himself. The materials of a complete autobiography might wellnigh be found in them, in language which could not be improved. The ardent and gifted young scholar, the accomplished and devoted professor, the cautious and conservative statesman, the sincere and earnest patriot, the exhaustless and consummate rhetorician are depicted in these volumes with the exactness of a photograph. The true man, the ever-obliging and faithful friend, the good citizen, are not less clearly delineated. It is too early to pronounce upon the permanent influence of such a career. His life must be taken as a whole, in order to form any adequate appreciation of its value. Certainly, there have been wiser and profounder statesmen among us, and scholars as learned and accomplished; but we think the annals of our country to the day of his death will be searched in vain for another so ready, prolific, and brilliant a writer and speaker, or for one who has done more both to adorn American literature and to advocate and advance every public interest and

patriotic cause. The statue of him by Story, ordered by his fellow citizens, and placed (by no means to advantage) in the Public Garden of Boston, portrays him in the relation to his times in which he will longest be remembered—as one whose every word and gesture was untiringly and grandly employed in animating his hearers to the best and loftiest ends.

Mr. Everett's repeated visits to Europe, and his residence in London as American minister for four years, afforded him an opportunity of becoming personally known and appreciated in other lands besides his own. Sir Robert Peel and Lord Aberdeen, Rogers, Hallam, and Macaulay, were among his warmest English friends. Lord Macaulay died with an unfinished letter to him on his table or in his pocket. He received the highest literary honors from Cambridge and Oxford at a time when those universities were more chary than of late in decorating Americans. Humboldt and Guizot were among his friends on the Continent. The Institute of France enrolled him as a corresponding member. At home he enjoyed the lifelong intimacy and confidence of Daniel Webster, whose collected works he edited and published in 1851 in six volumes, with a carefully written biography in the first volume.

In 1822, Mr. Everett married Miss Charlotte Gray, daughter of the Hon. Peter C. Brooks, a distinguished merchant of Boston, of whom he prepared an elaborate memoir, which is included in the third volume of his "Orations and Speeches." Two sons and a daughter survived him. ROBERT C. WINTHROP.

Everett (HORACE), LL.D., born in 1780, graduated at Brown University in 1797, settled as a lawyer at Windsor, Vt., became a prominent politician, holding important positions in Vermont. He was a member of Congress (1829–43), and was distinguished as a friend of the Indians. Died Jan. 30, 1851.

Ev'erghem, a Belgian town, a railway station in East Flanders. It makes cotton lace and beer. Pop. 6447.

Ev'erglades, a marshy region in Southern Florida, S. of Lake Okeechobee, itself resembling a great shallow lake abounding in low islands, which are covered with a dense jungle of pines, palmettoes, vines, and tropical trees, many of which are found only in this State and the West Indies. The water between the islands is from one to six feet deep, and is covered with tall grass, which grows from the bottom and gives the region a beautiful appearance. The Everglades will no doubt in time become valuable for the cultivation of bananas and tropical fruits. They abound in game. They are 160 miles long and 60 broad. There are about 300 Seminole Indians remaining here. The Everglades are elevated several feet above the sea, which often approaches within half a mile. Their drainage could therefore be easily accomplished.

Ev'ergreen, a post-village, capital of Conecuh co., Ala., on the Mobile and Montgomery R. R., 97 miles N. E. of Mobile. It has one weekly newspaper. Pop. of Evergreen township, 1760.

Evergreen, a township of Montcalm co., Mich. P. 489.

Evergreen [Lat. *sempervirens*], a term applied to trees and shrubs whose leaves are not deciduous, but persistent, retaining their verdure throughout the winter. Evergreen leaves are mostly thicker and firmer in texture than the leaves of deciduous trees. The greater part of the trees of the natural order Coniferæ are evergreen, as the pine and cedar. Among other evergreens are the holly, orange, ivy, myrtle, box, and laurel. In general, the duration of the life of leaves is in inverse ratio to the activity of their evaporation. According to W. B. Carpenter, "Trees and shrubs which are spoken of as evergreen do not really retain their leaves for more than a year; but they are not cast off until a new crop appears, and the exchange does not take place suddenly, but gradually." (*Vegetable Physiology.*) "There are some falling leaves," says De Candolle, "as those of firs, which remain two, three, or more years, but which ought not to be confounded with persistent leaves, although both constitute the permanent foliage of evergreen trees and shrubs."

The following is a list of the more important coniferous evergreen trees indigenous to the United States.

Common Names.	Botanic Names.
White Spruce	Abies alba
Hemlock	Abies Canadensis.
California Spruce	Abies amabilis
Douglass Spruce	Abies Douglassii.
Menzies Spruce	Abies Menziesii.
Mexican Spruce	Abies Mexicana.
Black Spruce	Abies nigra.
Red Spruce	Abies rubra.
Sabine's California Spruce	Abies Sabini.
California White Cedar	Libocedrus decurrens.
White Cedar	Cupressus thyoides.
Lambert's Cypress	Cupressus Lambertiana.
Great Coned Cypress	Cupressus macrocarpa.
Mexican Cypress	Cupressus Mexicana.
Red Cedar	Juniperus Virginiana
Great Flowered Magnolia	Magnolia grandiflora.
Balsam Fir	Abies balsamea.
California Noble Fir	Abies nobilis.
White Pine	Pinus strobus
Yellow Pine	Pinus mitis
California Yellow Pine	Pinus brachypterus.
California Nut Pine	Pinus edulis
Jersey Pine	Pinus inops
Scrub Pine	Pinus Banksiana.
Pitch Pine	Pinus rigida
Long-leaved Pine	Pinus australis.
Pond Pine	Pinus serotina.
Spruce Pine	Pinus glabra.
Mountain Pine	Pinus pungens.
Loblolly Pine	Pinus tæda
Lambert's Californian	Pinus Lambertiana.
Red Pine	Pinus resinosa
Bald Cypress	Taxodium distichum
American Yew	Taxus baccata Canadensis.
Florida Yew	Taxus Floridana
American Arbor Vitæ	Thuya occidentalis
Giant Arbor Vitæ	Thuya gigantea
Florida Torreya	Torreya taxifolia.
California Torreya	Torreya Californica.
Great California tree	Sequoia gigantea.
Redwood	Sequoia sempervirens.

Foreign coniferous evergreen trees common in the nurseries of this country:

Common Names.	Botanic Names.
Silver Spruce	Abies argentea.
Dwarf Alpine Spruce	Abies erunoniana.
Blue Spruce	Abies cerulea.
Norway Spruce	Abies excelsa.
Spruce, Himalaya	Abies morinda
Spruce, Mucronate	Abies mucronata
Spruce, New Holland	Abies Novæ Hollandiæ.
Spruce, Yew-leaved	Abies taxifolia.
Spruce, Narrow-leaved	Abies tenuifolia.
Chili Pine	Araucaria imbricata.
Chinese Lance-leaved Pine	Araucaria lanceolata.
Brazil Pine	Araucaria Brazilensis.
Bidwill's Pine	Araucaria Bidwillii
Moreton Pine	Araucaria Cunninghamii.
Norfolk Island Pine	Araucaria excelsa.
Graceful Pine	Araucaria gracilis
Cedar, African Green	Cedrus Africanus viridis.
Cedar, Deodar, silvery foliage	Cedrus deodara.
Cedar, Green Deodar	Cedrus deodara viridis.
Cedar of Lebanon	Cedrus Libani.
Mount Atlas Silvery Cedar	Cedrus Libani argentea.
Japan Dark-green Yew	Cephalotaxus adpressus.
Fortune's Chinese Yew	Cephalotaxus Fortunei.
Mountain Yew	Cephalotaxus montana.
Chinese Yew	Cephalotaxus Chinensis.
Japan Weeping Cypress	Cryptomeria Japonica.
Japan Dwarf Cypress	Cryptomeria nana.
Cypress, Australian	Cupressus Australis.
Cypress, Spreading	Cupressus expansa.
Cypress, Chinese	Cupressus funebris.
Cypress, Graceful	Cupressus gracilis.
Cypress, Weeping	Cupressus pendula.
Cypress, Pyramidal	Cupressus pyramidalis.
Cypress, Sacred	Cupressus religiosa.
Juniper, Silver-leaved	Juniperus argentea.
Juniper, Berry-bearing	Juniperus baccifornis.
Juniper, Bermuda Cedar	Juniperus Bermudiana.
Juniper, Chinese	Juniperus Chinensis.
Juniper, English	Juniperus communis.
Juniper, Cracow	Juniperus Cracovia.
Juniper, Himalaya	Juniperus excelsa
Juniper, Irish Spiral	Juniperus Hibernica.
Juniper, Hudson's	Juniperus Hudsonii.
Juniper, Japan	Juniperus Japonica.
Juniper, Phœnician	Juniperus Phœnicia.
Juniper, Sacred	Juniperus religiosa
Juniper, Swedish	Juniperus Suecica.
Juniper, Spanish Incense	Juniperus thurifera.
Fir, or Spruce, European Silver	Picea pectinata.
Fir, Weeping Silver	Picea pectinata pendula.
Fir, Kumaon Pindrow	Picea Pindrow.
Fir, Altaic	Picea Sibirica.
Fir, Mount Atlas	Picea pinsapo.
Fir, Nepal purple-coned	Picea Webbiana.
Pine, Austrian Black	Picea Austriaca.
Pine, Calabrian	Pinus Calabricusis.
Pine, Siberian Cembran	Pinus cembra.
Pine, Nepal short-leaved	Pinus Gerardiana.
Pine, Haguenea	Pinus Haguensis.
Pine, Aleppo	Pinus Halepensis.
Pine, Dwarf Mountain	Pinus pumilio.
Pine, Italian Stone	Pinus pinea.
Pine, Scotch Pine, or Fir	Pinus Sylvestris.
Yew, English	Taxus baccata
Yew, Silver-striped	Taxus baccata argentea.
Yew, Weeping	Taxus Dovastoni pendula.
Yew, Irish Spiral	Taxus Hibernica fastigiata.
Arbor Vitæ, Fern-leaved	Thuya asplenifolia.
Arbor Vitæ, Australian	Thuya Australis
Arbor Vitæ, Japan	Thuya Japonica.
Arbor Vitæ, Nepaul, or Tartarian	Thuya Nepalensis.
Arbor Vitæ, Chinese	Thuya Orientalis.
Arbor Vitæ, Siberian	Thuya Sibirica.

Everlasting Flowers, the common name of several genera of the order Compositæ, having flowers which if

dried and preserved retain their form and color many years. They are often called immortelles.

Ev'ersley (Charles Shaw-Lefevre), Viscount, D. C. L., an English liberal, was born in London Feb. 22, 1794, was educated at the University of Cambridge, and was admitted to the bar. From 1830 to 1857 he was a member of Parliament, and for eighteen years (1839–57) was Speaker of the House of Commons. He became Viscount Eversley in 1857.

E'versmann (Eduard Friedrich), a German traveller and naturalist, born in 1794, went to Bokhara with the Russian embassy in 1820, to the shores of the Caspian Sea in 1825, and afterwards to the Southern Ural, Caucasia, and Algeria. In 1828 he became professor of zoology and botany in the University of Kasan, and died there in 1860. He published several accounts of his travels.

Ev'erts (W. W.), D. D., a Baptist minister, born in Granville, N. Y., in 1815, graduated at Madison University in 1839, preached in New York City (1839–50), in Louisville (1852–59); since which time he has been a pastor in Chicago. He has published the "Pastor's Handbook," "Life of Foster," "Bible Manual," "Free Manhood," "Childhood, its Promise and Training," "Bible Prayer-book," and other works.

Evesham, a parliamentary borough of England, in Worcestershire, is on the navigable river Avon and in the beautiful Vale of Evesham, 15 miles S. E. of Worcester. It has remains of an abbey built about 700 A. D. It sends one member to Parliament. Here Edward, prince of Wales, afterwards Edward I., defeated Simon de Montfort and the barons in 1265. Pop. in 1871, 4887.

Evesham, a township of Burlington co., N. J. Pop. 3351.

Evic'tion [Lat. *evic'tio*, from *e* (*ex*), "out," and *vin'co*, *victum*, to "conquer"], the act of dispossessing one of his lands or tenements, as when a third person evicts a tenant by means of a title superior to that of the landlord, or a vendee by a title superior to that of the vendor. Technically, an eviction must be by judgment of law, but in the case of a tenant many acts done by the landlord to impair the enjoyment of the premises will amount to an eviction in law, and justify the tenant in leaving them; but in such cases he must actually leave, otherwise he cannot claim to have been evicted. When the grantee of premises is evicted, if the conveyance to him was with a covenant of warranty, he can recover from the grantor the consideration-money, with interest, but not, in general, the increased value of the premises, even if caused by improvements made by him on them. If evicted from part of the premises only, he recovers a proportionate part of the consideration. In case of a lessee, however, as the rent is regarded only a fair compensation for the use of the premises, and as it ceases on eviction, he can as a general rule recover only the expenses of defending his possession. When a lessee is evicted in part by one having a superior title, the rent is apportioned.

Evi'dence [Lat. *evidentia*, from *e*, "out," implying "clearness," and *video*, to "see"], in law, is the means of establishing an allegation made in a court of justice. In an action the respective parties make written statements of their cause of action and defence. The matter thus in dispute between them is called an issue. The object of evidence is to establish or disprove the propositions alleged. The result of the evidence is called proof. Evidence may be considered under a number of divisions: 1. Its nature and the doctrine of presumptions; 2. The rules that govern in the production and exclusion of testimony; 3. Its effect; 4. The instruments of evidence, including witnesses, and the mode of making use of them as well as writings.

1. *Its Nature, etc.*—The object of evidence is to establish a fact. It presupposes a disposition in the mind of a listener to believe upon sufficient grounds. Belief on the part of mankind is instinctive, yet this instinct is modified by the results of observation and reflection. When evidence is offered in a court of justice, it is assumed to be addressed to minds competent to give it such weight as its quality justifies. It may be either direct or circumstantial. It is said to be direct when it is offered simply to establish the fact which it concerns; it is circumstantial when its object is to lead the mind of the hearer to *deduce* or *infer* some other fact from it. In the case of circumstantial evidence the minds of the jury or judge, as the case may be, go through a process of reasoning to arrive at the principal fact in dispute. It must be resorted to with caution, in order that the conclusion arrived at may be sound and logical.

Reference may now be made to the subject of presumptions. These are of two kinds—of law and of fact. Presumptions of law are either conclusive or disputable. A conclusive presumption of law takes place when a legal conclusion is arrived at which no evidence is admissible to rebut. This doctrine is based largely on public policy, and leads to a series of artificial and arbitrary subordinate rules. An illustration is, that a child under seven years of age cannot commit a felonious crime. The doctrine of estoppel is another illustration. When evidence can be offered to rebut a presumption of law, it is said to be disputable. An instance is the ordinary rule in criminal law, that one charged with crime is presumed to be innocent until he is proved to be guilty, or that one having possession of stolen goods immediately after a theft became possessed of them unlawfully. Under this theory, when a state of facts is once established, it is presumed to exist until there is some evidence to the contrary. Thus, a man engaged in trade is assumed to follow the ordinary course of business, or the incumbent of a public office to perform its duties in the usual manner. Life is presumed to continue unless there is evidence of death, or sanity until evidence is offered to establish insanity. A presumption of fact is not a rule of law which can be announced to a jury as binding upon them, but in each case must be found by them as a matter of fact, though the court may direct their attention to the propriety of forming the conclusion. An illustration is the testimony of an accomplice, which is generally deemed to be untrustworthy without corroboration from other and trustworthy sources, and an observation to that effect may be made by the judge. Still, the jury has the legal power to find a verdict upon the uncorroborated testimony of an accomplice.

2. *The Rules which prevail as to the Production of Evidence.*—The leading rules are the following: Rule 1. Certain matters may be judicially taken notice of without proof; Rule 2. Evidence must correspond with the allegations in the pleadings, and be confined to the points in issue; Rule 3. Only the substance of the issue need be proved; Rule 4. The burden of proof is with him who holds the affirmative; Rule 5. The best evidence must be produced of which the nature of the case admits; Rule 6. Hearsay evidence is in general inadmissible; Rule 7. Testimony should in general concern matters of knowledge as distinguished from opinion (though to this rule there are well-established exceptions); Rule 8. Certain evidence, otherwise admissible, is excluded on grounds of public policy; Rule 9. In certain cases, principally by statute law, written evidence must be resorted to rather than oral; Rule 10. Oral contemporaneous evidence is not admissible to vary the terms of a written instrument. These rules require some explanation. It should be premised, however, that on a trial, with or without a jury, it rests with the judge to determine whether the evidence is admissible under these rules. Whichever way he may decide, the opposing party may except, and make his exception the subject of an appeal.

Rule 1. There are certain facts of general notoriety in respect to which it is not worth while to take up time to adduce evidence, such as the recurrence of the seasons. The same rule applies to the existence of foreign nations recognized by the executive power of the nation, and to general statutes of the legislature. Of such facts a court is said to take "judicial notice," and, if necessary, may resort for information to books and other sources of knowledge.

Rule 2. The second rule excludes all immaterial evidence, and confines the trial to matters in issue. Immaterial allegations in the pleadings cannot be proved. For example, evidence of the intent of a party would not be admissible unless intent was material; and the same remark may be applied to evidence of good or bad character. In an action to recover money loaned, evidence of the bad intent of the debtor in delaying payment, or of the creditor's bad character, would be plainly inadmissible, while in an action for slander the plaintiff's character would be to a certain extent in issue.

Rule 3. This rule means that the minor and unimportant allegations relating to the issue need not be established as stated. They are such as the statements respecting the time or place where an event occurred, or the value of an item of property. Still, even allegations in their nature unimportant may become material by the mode in which they are stated, as if they are made descriptive. In such a case a difference between the pleadings and the evidence, called a variance, may be fatal. The effect of this stringent rule has in a number of the States of this country been greatly modified as to civil actions by statutes of amendments. The criminal law is still disfigured by extreme technicality in this respect, and needs the hand of a discreet reformer, who, while he carefully preserves in favor of one accused of crime all necessary safeguards, at the same time subserves the interests of the public by removing all useless impediments to the due administration of justice.

Rule 4. Under this rule he who makes an allegation which is disputed, so as to be at issue, must establish it by evi-

dence. The burden of proof is usually with the plaintiff, though in some instances it devolves upon the defendant, as where he admits the plaintiff's case, but seeks to avoid its effect by new allegations—as, for example, infancy. The person who has the burden of proof has the right to open the case and close it. This in jury trials is often deemed to be a matter of much importance, so that each of the respective parties insists on an adjudication that the burden of proof belongs to him.

Rule 5. Under this rule evidence is divided into primary and secondary. If the primary evidence is accessible, it must in general be produced; if it be lost or destroyed, resort may be had to that which is secondary. Thus, where the law requires a contract to be reduced to writing, or where the parties have written out a contract which might have been oral, the written instrument must itself be produced if it can be obtained. The rule is relaxed in certain cases where public convenience may require it. For this reason a public record may be proved by an authorized copy, without the production of the record itself.

Rule 6. The word "hearsay" is infelicitous, including not only what is said, but what is written, or even acted. The rule means that evidence must be given in by one who is personally cognizant of the fact to be proved, and not by one who may have gained his knowledge at second hand, from the act or narration of another. Bentham distinguished between a "perceiving" and a "narrating" witness with the same general view. The reasons for excluding "hearsay" evidence are so obvious that it is unnecessary to refer to them. Great care must be taken in distinguishing between hearsay evidence and that which is original. Thus, when the very subject of inquiry is whether a certain thing was or was not said by a person, evidence that it was said is clearly admissible. So when a statement forms a part of a transaction, or, in technical language, *res gestæ*, evidence of it is not hearsay. Where the testimony is clearly hearsay, there are certain exceptional instances in which it is admissible, as in matters of public or general interest, or of ancient possessions, or of dying declarations in cases of homicide. It should be added that the admissions or confessions, when voluntary, of a party to an action are received in evidence against him on mixed grounds, partly as a substitute for more regular methods of proof, and partly as a branch of the law of *res gestæ*.

Rule 7. Under this rule a witness must in general testify only to facts of which he is personally cognizant, without giving his opinions as to their effect. There is a class of witnesses, termed "experts," who are allowed to give their opinions upon facts of which they have no personal knowledge. For example, the testimony of persons acquainted with the facts may be read over to the expert, and his opinion asked as to the conclusion which should be drawn from it; or a hypothetical question, embracing the facts assumed to be established, may be put to him. An "expert" is one skilled in a particular trade, art, or profession. An instance is a superintendent of an insane asylum as to matters connected with the subject of insanity. There are a few instances in which persons who are not experts are from the necessity of the case, or by a special rule of law, allowed to testify as to their opinions.

Rule 8. This rule shuts out evidence in a number of cases where strong reasons of a public nature demand that it should be excluded. A leading instance is that of confidential communications between an attorney and client, and similar communications between husband and wife. It also prevents a judicial inquiry into "secrets of state," and, to a certain extent, into the deliberations of judges in forming a judgment or of juries in arriving at a verdict.

Rule 9. There is a great statute in the English law, termed the "statute of frauds," requiring certain transactions to be evidenced by writing, such as conveyances or leases of land, wills of land, and some executory contracts, as, for example, contracts to convey land or to be answerable for the debt of another. These are but instances of a more extended class of cases. Without the writing as evidence these contracts or transactions cannot be established. It should, however, be added, that if such contracts, etc. have once been written and cannot be produced, their contents may be proved by oral evidence.

Rule 10. This is an inflexible rule, applicable to contracts, wills, etc. Even if a contract need not have been written, yet if the parties choose to have it so, no contemporaneous oral evidence can be offered to show different or additional terms. There is a conclusive presumption of law that the parties intended to merge all anterior and contemporaneous propositions in the writing. That is the sole repository of their intention; the rule, from the nature of the case, does not preclude oral proof of a subsequent modification of the contract, nor does it prevent the introduction of oral evidence to explain the writing. Thus, the meaning of technical words may be shown by the testimony of experts, and oral evidence may be used to show the circumstances surrounding the transaction, so as to place the court in the position of the parties. This is a rule of interpretation. It assumes that the instrument is valid. When the validity of the instrument itself comes in question the rule has no application. Oral evidence may accordingly be offered to show that the instrument is void. So if a clause has been omitted or inserted by mistake, a court of equity will, on sufficient oral evidence, rectify the instrument, or, in technical language, "re-form" it, and give it the form intended by the parties.

3. *The Effect of Evidence.*—In general, evidence is to be weighed by the jury or judge, as the case may be, and a decision to be rendered in view of all the circumstances of the case. In some instances its effect is governed by technical rules. This remark is particularly applicable to matters embraced under the head of estoppel. (See ESTOPPEL.) The evidence in this class of cases is conclusive. The most important instance of the application of this principle is that of a judgment recovered in a court of justice. Judgments are of two general classes—*in rem* or *in personam*. In the one case the action or proceeding is instituted against a "thing," such as a ship or article of merchandise, to fix its ownership, or to establish the *status* of a person, as to have an adjudication that he is a lunatic. The judgment itself accomplishes the result declared. The person in the case supposed becomes, in legal view, a lunatic, whether he be so in fact or not. So the ownership of the property is in the same way established, as in the case of the adjudication of prizes in time of war. The effect of the judgment is accordingly conclusive. By a fiction of law all persons are supposed to be parties to such a proceeding, and to be bound by it. An action *in personam* is brought against a person to obtain a judicial declaration or sentence concerning his duty or obligation. The sentence does not of itself accomplish the required result, but a mandate to an executive officer is necessary, in the nature of an execution. (See EXECUTION.) It is illustrated by an ordinary judgment for a sum of money. The sheriff proceeds to sell the debtor's property, and thus obtains the money. A judgment in this class of cases is only conclusive evidence upon the same subject matter between the parties to the action and those claiming under such parties, such as heirs and administrators. There must also have been an adjudication upon the merits of the case. Thus, if an action be dismissed because it is prematurely brought—*e. g.*, before a claim is due—a new action can be instituted. It is a further remark that the judgment is only conclusive upon matters really in issue, and therefore not upon such as were incidentally considered, nor upon matters that could be inferred by argument from the judgment. There is an admirable statement of the rule in all its branches by Lord Chief-Justice de Grey in the famous case of the Duchess of Kingston (20 Howell's State Trials, 538).

It should be added that in some cases the law gives to certain acts the force of *primâ facie* evidence, which, as the phrase implies, is liable to be rebutted. Thus, a promissory note is presumptively made upon a valuable consideration. Statute law frequently declares that a particular transaction shall have this force. The rules of evidence are under the control of the legislature so long as they do not impair vested rights or violate in any manner constitutional law in its letter or spirit.

4. *The Instruments of Evidence.*—These are either witnesses or writings. (1.) *Witnesses.*—A witness, when within the jurisdiction of the court, must in general attend in person. He can be compelled to attend by a writ termed a subpœna, and in the same way to bring writings which are required. When beyond the jurisdiction, his testimony is taken under a commission issuing from the court in which the case is pending. This matter is in some respects governed by statute, though in some of the courts, as in equity and admiralty, there is an inherent power to issue commissions. The testimony, when taken in the foreign country, is returned to the court, subject to any objections which may properly be taken to it. Certain classes of persons are excluded from testifying. The rules upon this subject are to some extent arbitrary. They have been modified in recent times by statute. Thus, parties to the action were at one time wholly excluded in the courts of common law. They are now by statutes generally admitted. The same remarks may be made as to persons having a pecuniary interest in the event of the litigation. Persons are still incompetent who have a defect of understanding, or who are supposed to be insensible to the obligations of an oath. Thus, persons convicted of an infamous crime are excluded from testifying in the courts of the State where the conviction took place. The tendency of modern law is to allow as wide a range as possible, and to permit objections to witnesses which were formerly grounds of exclusion to be only urged as affecting the value of their testimony. In technical language the

objection does not go "to the competency, but to the credibility of the witness." The examination of witnesses is governed by rules which are to some extent discretionary, and in other respects absolutely binding. The principal rules are these: *a.* Leading questions are not, in general, to be asked on the direct examination. *b.* The party calling the witness cannot attack his character, though he may show by independent testimony that his version of the facts is not correct. *c.* The range of cross-examination is much wider than the direct, and leading questions are permissible. A witness cannot on cross-examination be asked a collateral question for the purpose of contradicting him in case his answer should be untrue. He may, however, be asked, under proper limitations, with a view to contradiction and the discredit of his testimony, if he has not given out of court a different version of the facts from that to which he now testifies, and in the same way as to expressions of hostility towards the party against whom the testimony is given. *d.* A witness is privileged from answering a question if such answer would tend to convict him of a crime or to subject him to a penalty or a forfeiture, though this rule would not extend to the case where he might simply be made liable in a civil action for a debt, etc. How far he can refuse to answer a question which if answered would tend to degrade him in the estimation of his fellows, is not fully settled. *e.* The character of a witness may be attacked by the opposing party, either by direct evidence of his bad character, or rather reputation, or by showing that he has from time to time given different versions of the facts. *f.* A cross-examination is to be confined to the matters brought out on the direct examination, and the same remark is applicable to the re-direct and subsequent examinations. (2.) *Writings* for the purposes of the law of evidence are either public or private. Public writings are either judicial or not judicial. The law provides compulsory modes of producing public writings for the purposes of testimony. Copies are in general resorted to, on grounds of public convenience. The officer having the document in custody has, in general, the power to give a certified copy, which is admissible in evidence. Copies of judicial records are of three varieties: exemplified (a copy either under the great seal of state or under the seal of the court), office (certified by the clerk or other custodian), or sworn. A sworn copy is authenticated by the testimony of a witness who has compared the original with the copy. An act of Congress, authorized by the U. S. Constitution, provides a convenient mode of authenticating a judgment or decree of the courts of record of one State to be used in the courts of another State. Should a record be destroyed, its contents may be proved by oral evidence. A private writing is proved by the production of the writing itself, and its existence established by the testimony of a witness. Where the writing cannot be produced, secondary evidence of its contents may be given. In the special case where it is in the possession of the opposite party reasonable notice should be given to him to produce it at the trial. If he fails to produce it, secondary evidence may be given as before. When a private writing is executed in the presence of a witness subscribing his name at the request of the maker of it, this witness, called a "subscribing witness," is the proper person to prove it. If he be dead, or for any sufficient reason cannot be produced, his handwriting may be proved, with some evidence to identify the party to the action as being the person who executed the instrument. When there is no subscribing witness, the proper course is to call a witness acquainted with the handwriting of the maker of the instrument to testify that in his opinion the instrument or the signature is in the handwriting of the party. Though this is matter of opinion, it is admitted from the necessity of the case. Knowledge of the handwriting may be acquired in various modes, usually by seeing the person write or by having transactions or correspondence with him. The testimony of experts as to handwriting is in some cases admitted, though the law as to the extent to which they may be examined varies in the different States. In some of the States there are convenient statutory modes of proving private writings. A single instance may be cited from the law of New York, which allows nearly every contract, if acknowledged by the maker before an authorized officer, such as a notary public, to be put in evidence without other testimony by way of authentication.

The final remark may be made, that the rules of evidence, though positive and in some respects arbitrary, are largely based upon public convenience, and are adapted to the wants and habits of the community.

T. W. Dwight.

Evidences of Christianity, The. The Evidences of Christianity, by the very fact of their existence, afford a strong presumption in its favor. They place it before the world as at least claiming to be founded in truth and suited to the reason of man. Had it made its way by mere force and policy, or did it now require assent without testimony and argument, there would be no need even to investigate its merits. It might be classed at once with the false religions which are confessedly without reasonable evidence, if not beneath discussion. But in distinction from all other systems it possesses a recognized body of proof which has been accumulating for eighteen centuries under the most varied and searching criticism, and which, when examined, is found to be all that the case admits or that an intelligent inquirer could demand. Such an inquirer may therefore be challenged at the threshold to acquaint himself with the history of the Christian evidences before he proceeds to judge them in detail.

History of the Christian Evidences.—The history of Christianity is, in one view, but the history of its evidences. Externally, at least, its course through the world has been marked by successive crises, when it encountered various forms of incredulity which it became necessary to repel with suitable evidence; and out of every such conflict it has emerged with a triumphant vindication of its claims and a fresh contribution of proof to after generations.

Its first conflict was with Judaism. On its native soil and at its very origin it excited the bitter unbelief of the Jewish rulers and people, who repudiated it as an impious caricature of their own ancient religion, stigmatized its author as an impostor or false Messiah, and at length compelled him by the death of the cross to become the first great martyr to its truth. Judaism, as a distinct system, from that moment declined into a mere dead tradition, and has since, by its own predicted fate, served but as an unwilling witness for that Christianity which has been spreading over the globe and becoming the common heritage of all nations and races. The life and death of our Lord, including his discourses, parables, and miracles, as recorded in the four Gospels, constitute the evidences of Christianity afforded at its origin.

Its next conflict was with Paganism. No sooner had it been proclaimed outside of Judæa as a gospel to the nations than it encountered the decaying religions of Greece and Rome, which desperately rallied against it as a common enemy. But its course from city to city was marked with crowds of converts, as well as with persecutions and conflicts, everywhere accelerating the decline of those old mythologies, which now figure only in the classic literature made tributary to its own defence and illustration. The planting and training of the Church, as narrated in the Acts and Epistles of the apostles, together with the Apologies of Justin, Tatian, Athenagoras, and Theophilus, yield the evidences belonging to this period.

Its next conflict was with Philosophy. So long as it was contending with mere Jewish and heathen superstitions the learned class could treat it with disdainful silence, such great writers as Plutarch, Seneca, and Tacitus alluding to it only in the most distant manner; but as its exclusive claims gradually became known, its advance was met by an infidel wing of the Neo-Platonic school, led by Celsus, Porphyry, and Hierocles, who assailed it as a vulgar imposture, and at length provoked the series of bloody persecutions which filled the cities of the empire with Christian martyrs. Its apparent defeat, however, was followed by a victory almost ruinous. It had already won from the very ranks of Plato its first great apologist, Justin Martyr, and it now wrested so much of philosophy itself as could be wrought into its own theology; and at length appeared upon the throne of Constantine as the visible head of a new Christian civilization. Besides these worldly trophies, its direct evidences for this period are to be found in the testimony of the martyrs and the apologetical writings of Tertullian, Clement, Origen, Eusebius, Cyril, Arnobius, Lactantius, and Augustine.

Its next conflict was with Barbarism. In the Dark Ages following the barbarian conquest and the wreck of the Roman empire, though it was now deprived of all earthly aid, it subdued the rude religions of the North as it had already vanquished the classic mythologies of the South, and treasured up from the civilization of the past all that was valuable for that of the future. While contending with such savage foes it could have no other evidences than such as appeared practically in the Germanic missions and in the great Christian schools of the Middle Ages.

Its next conflict was with Mohammedanism. The Saracen was invading its domains with the sword and the Koran from the East to the shores of Spain; but the fierce Goths whom it had trained into Christian knights now by successive crusades battled for the tomb of the Saviour, until Europe was delivered from the infidel. Its evidences for this epoch were all that could be expected—the exploits of Christian chivalry, the prizes wrested from Arabian learning, and the apologetical writings of the Schoolmen against the Jews and Mohammedans in Moorish Spain.

Its next conflict was with modern Rationalism. Divided at the Reformation into Catholicism and Protestantism, it encountered a treacherous foe which for several centuries past, under various guises, has been subjecting its divine revelations to the test of mere human reason. But hitherto the strength of its evidences has only been proved by each successive assault. The Italian naturalists of the sixteenth century, such as Pomponatius, Cæsalpin, and Cremoninus, who held Aristotelian opinions subversive of revealed religion at the very court of Rome and under feigned respect to the Church, wrought their own defeat by their shameless hypocrisy and vice. The English deists of the seventeenth century (such as Herbert, Hobbes, and Toland), and of the eighteenth century (such as Collins, Tyndal, and Bolingbroke), who professed mere natural religion as essential Christianity, were so completely repulsed by the great apologists, Cudworth, Bentley, Berkeley, and Butler, that their very works have become obsolete or linger only as brilliant names in literature. The French atheists of the last century, such as Helvetius, Diderot, and D'Holbach, who assailed Christian morality itself with a sensual fatalism, only precipitated that terrible Revolution which has made them infamous as enemies of civilization, no less than of religion. The German pantheists of the present century, such as Strauss, Bauer, and Feuerbach, who have been striving to resolve Christianity into mere mythology, were routed upon their own ground and with their own weapons by such learned and acute writers as Neander, Ebrard, and Ullmann. And it is safe to predict that the sciolists of our own day, who are opposing it with science falsely so called, are but ensuring a like failure and defeat.

But the still remaining and perhaps final conflict is to be with modern Heathenism. Having developed for itself in the western nations of Europe and America during the last eighteen hundred years a civilization the highest the world has yet ever seen, it would be strange if it could not now cope with those eastern nations of Asia and Africa which meanwhile have remained stationary or relapsed to a savage state. And accordingly, for the last half century it has been slowly enveloping the globe with a network of missions, which, in connection with advancing science, commerce, and diplomacy, already betokens the ultimate triumph of Christian civilization over heathen barbarism throughout the earth.

Classification of the Christian Evidences.—On reviewing now the evidences which have thus been accumulating during this exciting history, we at once become embarrassed by their richness and fulness. Much ingenuity has, in fact, been exercised in digesting and arranging them, but the most common and serviceable classification is that by which they are divided as *external* and *internal*, with suitable subdivisions.

The external evidences are such as relate to the fact or existence of Christianity, rather than to its nature or system—the mere credentials of revelation as distinguished from its contents. They will naturally distribute themselves into the following groups: 1st, *Prophecies*, which have been fulfilled in the course of ancient empires, in the coming of Messiah, in the fortunes and fate of the Jews, and in the progress of the Christian Church: 2d, *Miracles*, which were wrought by prophets and apostles in attestation of their divine commission as teachers, disclosed in the life and death of Christ, the Son of God, and confirmed by the supernatural success of Christianity in the first age; 3d, *Historical Testimonies* to the authenticity and genuineness of the sacred writings, afforded not only by undesigned coincidences among them, but by contemporaneous heathen literature and by modern antiquarian research. Collections of the first kind of evidence may be found in the works of Newton and Keith; of the second, in those of Watson, Sherlock, Lesley, and Campbell in reply to Gibbon, Hume, and Paine; and of the third, in those of Lardner, Paley, Norton, Greenleaf, and Rawlinson.

The internal evidences are such as appear in Christianity itself, in the purport of the revelation which has been so miraculously attested. An argument for its divine excellence may be traced in all that distinguishes it from other mere human systems: 1st, in its *doctrines*, transcending the highest philosophy, such as the existence, perfections, and policy of the Creator, the origin of the world, the scheme of redemption, the state and destiny of man; 2d, in its *precepts*, surpassing the purest ethics, such as the Ten Commandments, the Sermon on the Mount, the counsels of the apostles; 3d, in its *examples*, unapproached by worldly heroes, such as those of evangelists, saints, and martyrs, and, above all, the immaculate Jesus himself; 4th, in its *effects*, not only upon the welfare of individuals, but upon the interests of society, as seen in works of charity and philanthropy, in the arts of peace, in humane laws and free institutions, and in the entire civilization which for centuries it has been unfolding. Specimens of such arguments may be found in the treatises of Jenyns and Warburton, of Archibald Alexander, Hopkins, and McIlvaine, and of Luthardt and Delitzsch.

Still further classes of evidence are of a mixed nature, being partly external and partly internal, and serving to show the connection and consistency of Christianity with other facts and truths. They also may be reheated under several heads: 1st, *Experimental* evidences, acquired by those who have personally tested in their own faith and practice the doctrines, precepts, and promises of the gospel, and thus offer new and original testimony; 2d, *Scientific* evidences, collected from the sciences which illustrate the existence and attributes of the Deity, and confirm the incidental allusions of Scripture to physical, mental, and moral phenomena; 3d, *Philosophical* evidences, derived from right reason and large experience as to the probable existence of a Divine government, a future state, a supernatural revelation, and a scheme of redemption, such as are found in the Scriptures, and also from the view of religion and nature as but consistent parts of one system, having the same Author. Examples of such high orders of evidence may be seen in the works of Locke, Browne, Butler, Paley, the Bridgewater Treatises, and the recent Bampton Lectures.

These various classes of evidence, when grouped together in one view, tend to produce a conviction which has been well likened by Bishop Butler to what is called the *effect* in architecture or other works of art. Examined separately, they may excite as little emotion as scattered stones upon a plain, but when combined, as they have been by this great architectonic genius, in one compact, cumulative argument, their resulting impression is like that of the same materials after they have been chiselled and fashioned into a magnificent building. But we already trench upon the next topic.

Logic of the Christian Evidences.—A far more important question than the mere classification of these evidences is that of their logical nature and value. Viewed from this point, they must ever take rank as the highest branch of applied logic, as well for the difficult problems which they involve as for the kinds of reasoning employed. And the practical bearing of the inquiry is shown by the fact that different apologists, in treating of the evidences, have more or less consciously exaggerated one class of them at the expense of the other, until, like a divided army wrangling in the face of an enemy, they have allowed infidels to involve both of them in doubt and suspicion. Of the two evidential schools which have thus taken opposite grounds, the one would render Christianity reasonable, the other present it as simply credible; the one would claim for it demonstrative evidence carrying full conviction, the other seek only probable evidence accumulating towards certainty: the one would dwell upon the internal philosophical proof, the other upon the external historical testimony; and at length the one ends in testing the whole content of revelation by mere reason, whilst the other virtually destroys all rational conditions of faith. The former method has been successively pursued to its extreme by Descartes, Clarke, and Wolf, and the latter by Butler, Chalmers, and Mansel.

It is enough here to assert the validity of both methods within the limits they impose upon each other. Each has had its value at different times and for different minds. The primitive apologists needed the external evidence for the Jews, who required a sign, as well as the internal evidence for the Greeks, who sought wisdom. And from that day till the present there have been infidels who were won by the doctrine and example of Jesus before they could admit his miracles, as there have been believers who ceased to find difficulties in Scripture after they had accepted it as an attested revelation. The simple truth is, that neither kind of proof can be spared from the high argument, and that both must be ultimately combined in order to ensure full conviction.

At this point the logical question we are considering begins to involve an ethical or moral element. It should be carefully observed that the apparent deficiency in the Christian evidences neither necessitates unbelief nor releases from obligation. On the contrary, the inquirer simply becomes accountable in proportion to the evidence perceived and the interests at stake. He is still to be tested and judged by the light which he has. Moreover, his incredulity may be his own fault. It is certain that the Christian evidences have hitherto proved sufficient for the greatest minds of the race. Are they now on the wane or on the increase? This is the remaining question.

Progress of the Christian Evidences.—A distinguished mathematician of the seventeenth century, John Craig, professed to calculate, on the hypothesis that the suspicions against historical evidence increase with the square of the time, that the evidence of Christianity will become extinct about the year 3150, when the Son of man will come and no longer find faith on the earth. And a school of

modern skeptics, including poets as well as philosophers, is already sighing over the decay of Christianity as but the last of the world's mythologies, destined to be superseded by the perfect religion of the future. If all that is meant by such writers is the decay of their own Christian faith, it need not be denied that many restless, speculative minds are breaking away from their moorings in false creeds and corrupt systems claiming to be Christian; but if the apprehension is that Christianity itself is dying out or losing its hold upon the world, such forebodings are to be no more seriously treated than the outcries of men losing their anchorage who fancy it is the immovable shore and not their own little vessel that is drifting away. Christianity has in fact lost nothing of the evidence which it has been accumulating since the time when first its miracles were wrought and its prophecies spoken. Not only does the testimony to those miracles remain unimpeached, not only is the fulfilment of those prophecies still passing before our eyes, but the human sciences since then unfolded are yielding it a new class of evidences, affording it fresh confirmation and illustration, and commending it to the highest intellect and culture of the time; and the reasonable presumption is that, one after another, they will yet corroborate all revealed facts and doctrines, until everywhere there shall be an intelligible triumph of the Divine through the human reason over all earthly error and sin.

That such an increase of evidence in this quarter is probable may be argued from the very nature of science and revelation as complementary factors of knowledge. It is inconceivable that the word of God should contradict his works, or that human reason could supersede a divine revelation; and when any discrepancies appear between Nature and Scripture, we must simply assume that there has been some wrong induction from either or both of them, and that ultimately, after the whole truth is known, they will confirm and illustrate each other. This has, in fact, been the result of past conflicts between the scientific and religious parties. Geography, in the early Church, repudiated the idea of an inhabited globe as contrary to the Scriptures, but ships now carry the same Scriptures to the antipodes. Astronomy, during the Middle Ages, described the heavens as huge crystal spheres revolving about our earth, but the very same heavens, as devoutly interpreted by Kepler, Newton, and Herschel, still declare the glory of God. Geology, of late years, has seemed inconsistent with the long-received interpretation of Genesis, but the story of the earth itself, as read by Miller, Hitchcock, and Guyot, still tells how it was made in six days. Anthropology, at the present moment, is full of conflicting theories, some of which menace the Scripture doctrine of the first Adam, but he must simply prejudge the whole question against all precedent who asserts that man was not made in the image of God. And in the region of the mental, moral, and social sciences, where the need and fact of a revelation are so much more obvious, the likelihood increases that there will hereafter be still higher and grander illustrations of Christian doctrine.

It is an encouraging sign of progress in the evidences of Christianity that so many organized efforts are on foot for their promotion, and some of them in the interest of true science as well as of religion. The Royal Society itself was founded by philosophers and divines who vindicated the consistency of natural with supernatural knowledge. Other institutions have followed, expressly designed for the defence of the Christian religion, such as the Boyle Lectures, the Bampton Sermons, the Bridgewater Treatises, the Burnet Essays in Great Britain, and the Lowell, Graham, and Ely Lectures in this country, together with more permanent educational appliances, such as chairs of Christian apologetics in divinity schools and of science and religion in our colleges. And the literature which has grown up in connection with these institutions, and by other independent efforts, is already of surprising extent and richness. Notices of this literature may be found in the appendix to Farrar's "Critical History of Free Thought," and the Abbé Migne has published a series of twenty volumes, 4to, entitled "Demonstrations Evangéliques," containing a full collection of the principal evidential treatises, of all schools in all ages, chronologically arranged, as a work equally important to the infidel, to the skeptic, and to the believer.

CHARLES W. SHIELDS.

E'vil, the total or partial absence or negation of good, and the presence of imperfection, suffering, or sin. The question of the origin of evil has in every age attracted the attention of thoughtful minds. The Zoroastrians and Gnostics tried to solve it by the dualistic theory of the opposition of a good and an evil principle. Others have maintained that evil is a necessary part of the Divine economy, and that under the superintendence of Infinite Wisdom evil will result in the highest possible good. It seems certain that moral freedom itself implies at least the possibility of an evil choice, so that evil must potentially exist where goodness exists. The solution of such questions is, however, beyond the power of any finite mind.

Evil Eye, the mysterious power of injury which in former ages was generally ascribed to the look of a malevolent person. The Greek and Roman classics contain numerous references to this belief, which was also very common in the Middle Ages in Europe. In Mohammedan and uncivilized countries this superstition is still almost universal, and it is by no means extinct among the peasantry of more civilized lands. It especially prevails in Western Africa. It is perhaps based upon the supposed powers of fascination possessed by serpents, of which much exaggerated stories were told and believed. Charms were much worn to prevent the mischief which it was believed could be done by the evil eye, which was considered especially dangerous to young children.

Ev'olute [for etymology see EVOLUTION], literally, "something unfolded or unwrapped," in mathematics, is a curve, plane or otherwise, around which, if a flexible and inextensible string be wrapped, and then unwrapped under tension, there result other parallel curves called *involutes*, one of which is described by every point of the tense string in unwinding. Every plane curve has its plane evolute, besides an infinite number of helical evolutes lying in the curved surface of the solid generated by the motion of the given plane curve parallel to itself. The common cycloid, the epicycloids, and the hypocycloids have plane evolutes exactly similar to themselves, but inverted in position. The logarithmic spiral is the only curve having all its evolutes similar to itself.

Evolu'tion [Lat. *evolu'tio*, from *e*, "out," and *vol'vo*, *volu'tum*, to "roll," whence *evol'vo*, to "unfold" or "evolve"], the act of unfolding, development; in algebra and arithmetic, the extraction of roots; in other words, the inverse operation to involution. The object of evolution, therefore, is to ascertain the quantity which multiplied by itself a stated number of times yields a given result. In a wider sense, evolution may be regarded as synonymous with the solution of a binomial equation, for it is obvious that the n^{th} root of any number a satisfies or is a root of the equation $x^n - a = 0$. This root is indicated by the symbol $\sqrt[n]{a}$ or $a^{\frac{1}{n}}$.

Evolution, Hypothesis of; also called **The Theory of Development.** According to this, in its simplest form, the universe as it now exists is the result of "an immense series of changes," related to and dependent upon each other, as successive steps, or rather growths, constituting a progress; analogous to the unfolding or evolving of the parts of a growing organism. Evolution is defined by Herbert Spencer as consisting in a progress from the homogeneous to the heterogeneous, from general to special, from the simple to the complex; and this process is considered to be traceable in the formation of the worlds in space, in the multiplication of the types and species of plants and animals on the globe, in the origination and diversity of languages, literature, arts, and sciences, and in all the changes of human institutions and society.

History.—Faint gleams only of the idea of evolution appeared among the ancients. An old Egyptian cosmological myth was that of a chaotic or mundane egg, from which all things successively emerged; with the belief, also, that repeated creations and destructions of the world have occurred. Thales taught that in the beginning all matter was in a fluid state. Anaxagoras held that all consisted at first of atoms, infinitely numerous and eternal; among which orderly arrangement was produced by a shaping *Nous* or intelligent Power, infinite and self-existent. Opposed to this conception was that of Democritus and Epicurus, as represented in the poem of Lucretius, "De Rerum Naturâ," according to which *chance*, not intelligence, wrought, in infinite time, out of numberless atoms, all existing things. Not far removed from this was the notion of Empedocles, mentioned by Aristotle (*Phys.* ii. 8), that many monsters were formed by the spontaneous efforts of nature before man appeared. More clear seems the reference to creative development in the words of David (Psalm cxxxix.): "My substance was not hid from thee, when I was made in secret, and curiously wrought in the lowest parts of the earth. Thine eyes did see my substance, yet being unperfect; and in thy book all my members were written, which in continuance were fashioned, when as yet there was none of them."

Leibnitz, in modern times, first definitely proposed the opinion that the world was once in a fluid condition (*Protogæa*, 1693). De Maillet (who died in 1738) and Wright of Durham, as well as, perhaps, Lambert, preceded Kant in expanding this thought. But Kant, in his "Theory of the Heavens" (1755), originated the nebular hypothesis.

Laplace (*Système du Monde*, 1796, and *Mécanique Céleste*, 1799–1825) elaborated this into a theory of the solar system; while Sir William Herschel (*Proc. Royal Society*, 1811) gave it a nearer approach to perfection in its general *cosmic* relations as a theory of the stellar universe. Sir John Herschel's hypothesis of "sidereal aggregation" presents a further modification of this. (See NEBULAR HYPOTHESIS.)

In biology, Buffon (*Histoire Naturelle*, 1749–88) is credited with distinctly advocating the transmutation of species. The most important beginning, however, of those inductions which have made possible the science of embryology, and have contributed most largely to the general theory of development, was that of Wolff (*Epigenesis*, 1759; *Theoria Generationis*, 1764). He first discerned the importance of the transmutations of structure and form which the parts of plants and animals undergo, by means of which, from almost formless seeds or eggs, come their diverse and complex organisms. Goethe (*Metamorphose der Pflanzen*, 1790) apprehended, independently, the same truth. Oken (*History of the Development of the Intestinal Canal*, 1805), Pander (1817), and, still more important, Von Baer (from 1819), carried out this idea as an extensive generalization, supported by numberless facts. Many other laborers have since worked in the same field.

In like direction have tended the results of inquiries into the ultimate elementary forms and proximate materials of animal and vegetable tissues: Schleiden and Schwann (1838) showing the *cell-form* to be common to both kingdoms in all their classes and orders; and Von Mohl and Max Schultze (1850–61), that a *protoplasmic* material, similar but not identical, is found in them all. (See CELLS and PROTOPLASM.)

In regard to the transmutation of *species*, Lord Monboddo in 1774 suggested the possible origin of man from the ape. With more scientific ability and knowledge, Lamarck (*Philosophie Zoologique*, 1809) proposed the hypothesis of organic development, which is chiefly associated with his name. One of his leading conceptions was that of the elevation of an animal (*e. g.* ape) to a higher range of faculties and appropriate organs by the prolonged and repeated *efforts* made by it to attain to conditions and advantages just within, or, at first, beyond, its reach. Dr. Erasmus Darwin (author of "Phytologia," "Zoonomia," etc.) about 1794–95 published speculative views containing at least the germ of the "Darwinism" of to-day. Dr. W. C. Wells proposed the application of natural selection to the natural history of man in 1813. W. Herbert in 1822 asserted the probable transmutation of species in plants. Prof. R. E. Grant advocated the same opinion about 1826.

Immediately connected with this progress of investigation were some important inquiries concerning the *correlation of forces* in nature, and the conservation or "persistence of force." First in the order of generalization or logical discovery on this subject are to be named B. Thompson (Count Rumford), 1798–1806, and Oersted, 1812–20; next to these, Seguin of France, Grove and Joule of England, Mayer of Germany, and Colding of Denmark; all of whom about 1842 announced, independently of each other, the idea of the essential unity of force, as involved in the mutual convertibility of the "modes of motion," observed by us as mechanical movement, heat, light, and electricity, into each other, under changed conditions. Since that time the correlations of the physical forces have been studied especially by Helmholtz, Faraday, Henry, and Tyndall. Vital force has been regarded as belonging to the same series of correlations in the writings of Liebig, Carpenter, Hinton, Waters, Barker, and others; and even mind-force is so included by Morell, Laycock, and Maudsley, as well as by Moleschott, Büchner, and other materialists.

Returning to the path of biological inquiry, we find that Geoffroy St.-Hilaire contended against Cuvier, in the early part of the present century, in favor of the transmutation of species. Popular interest in this subject was awakened by the publication, in 1844, of the "Vestiges of Creation," an anonymous work showing great ingenuity, but only a moderate acquaintance with the facts of science. Alexander Humboldt also, in 1844, declared his conviction that species are not immutable. Richard Owen, in 1859, referred to the struggle for existence as a cause of destruction of types least fitted for the conditions around them, and proposed about the same time the theory of the origin of species by "derivation" in a pre-ordained succession. Naudin, a French botanist, and Prof. Asa Gray of Cambridge, Mass., as early as 1856, drew somewhat similar inferences from their observations. More prominently, however, than any other since 1852, has the name of Herbert Spencer been connected with the theory of development, both in cosmology and biology. His "First Principles of Philosophy," "Illustrations of Universal Progress," and "Principles of Biology" have, with much labor both of synthesis and analysis, and great adroitness of reasoning and clearness of expression, wrought out what may be called a philosophy of evolution. Baden Powell of Oxford, England, in an able work on the "Unity of Worlds," in 1855, argued forcibly for the probable *continuity* of the process of creation throughout time. Alfred R. Wallace and Charles Darwin, in 1858, separately proposed the hypothesis of the origin of species by spontaneous variation, and the survival of the fittest through natural selection and the struggle for existence. In 1859 appeared Darwin's treatise on the "Origin of Species." (See DARWINISM.)

Strenuous opponents as well as advocates of the views above referred to have not been wanting. B. Peirce, R. Proctor, and others among astronomers have found serious difficulties in the way of adopting the nebular hypothesis as a finality. Organic evolution, including the transmutation of species, has been opposed by De Blainville, Milne Edwards, Sedgwick, Brewster, Balfour, Agassiz, Barrande, Dana, and Dawson. Besides those already named, it has been accepted in some form (not always that of Darwin) by Huxley, Vogt, Fritz Müller, Hæckel, Gegenbaur, Mivart, Hooker, Lubbock, and others in Europe, and by Clark, Cope, Hyatt, Hayden, and other naturalists in America. Among its ablest defenders has been Prof. E. L. Youmans. (See an "Exposition of the Development Hypothesis" by this author, and an admirable "Criticism" of the same, in "Johnson's Natural History," by Julius H. Seelye, D. D.) A majority of the scientists of the present day are on the side of the general theory of evolution. "Scarcely a single competent general naturalist," wrote in 1873 Prof. Wyville Thomson of Edinburgh, "fails to accept it, in some form or other." In the words of Prof. Youmans (*Popular Science Monthly*, Nov., 1872), "Darwin may be in error, Huxley may be wrong, Mivart may be wide of the mark, Hæckel may be mistaken, Cope may misjudge, and Spencer be at fault; but, in common with a large and increasing body of scientific men, they are all agreed as to one thing, that evolution is a great and established fact—a wide and valid induction from the observed order of nature, the complete elucidation of which is the grand scientific task of the future."

The application of the idea of development to sociology and history has been made by Herbert Spencer, J. W. Draper, and Bagehot, although earlier suggested by Herder (*Ideas of the Philosophy of the History of Mankind*) about the beginning of the present century. George Darwin has written recently upon development in dress; and Dr. James Ross upon natural selection in the causation of diseases (*The Graft Theory of Disease*, 1872). In the above list of authors, moreover, we have not mentioned several of eminence who have written especially upon the relation of the theory of development to theology; as Leifchild (*Higher Ministry of Nature*), the Duke of Argyll (*The Reign of Law*), and Dr. McCosh (*Christianity and Positivism*). (See, also, *The Evolution of Life*, by H. C. Chapman, 1872, and *Philosophy of Evolution*, by B. T. Lowne, 1873.)

Without space in this work for an exhaustive discussion of the subject of evolution, its importance requires a brief statement of the main elements of the inquiry.

Is Progress a Fact in Nature? Cosmologists and naturalists are all agreed upon this. In the language of the Duke of Argyll, "It is as certain as any fact of science that creation has had a history. It has not been a single act, done and finished once for all, but a long series of acts—a work continuously pursued through an inconceivable lapse of time. It is another fact, equally certain, respecting this work, that as it has been pursued in time, so also it has been pursued by method. There is an observed order of facts in the history of creation, both in the organic and in the inorganic world." Prof. Leconte asserts 390 coincidences in the solar system which are conformable to the nebular hypothesis. Some experimental support for it has also been afforded by the physicist Plateau. Lord Rosse's telescope diminished for a time the strength of the evidence in its favor by resolving many nebulæ into star-clusters, and leaving it in doubt whether there were any really consisting of unorganized "star-dust" or "world-stuff." Huggins, however, with the spectroscope, ascertained in 1864 that a nebula in the constellation Draco consists of gaseous matter; and since that time several others have been found to have that character. (See SPECTROSCOPE.) The spiral form of a number of nebulæ, and the annular shape of others, agree well with the rotary movement supposed in world-formation according to the nebular hypothesis. Some astronomers also consider that a sudden appearance in τ Coronæ, observed in 1868, indicated an alteration in the substance of that star, such as the incandescence of a gaseous material like hydrogen would produce. R. Proctor has written upon "star-drifts," showing a certain orderly arrangement of the bodies in space outside of our solar system. The spectroscope has contributed much towards the theory of cosmic development, by exhibiting

the close correspondence in the material composition of all the worlds. Durocher also (*Essai de Géologie Comparée*, 1857) proved the originally molten condition of our earth's surface by a careful comparative study of the specific gravities and the order of successive deposition of crystalline rocks. In organic nature on the earth, geology, zoology, embryology, and botany unite in asserting progress. (See GEOLOGY.) Prof. Dana, one of the highest authorities in natural science, and an opponent of the development hypothesis, may be quoted to this effect (*Text-Book of Geology*, pp. 250, 255): "Life commenced among plants in seaweeds, and it ended in palms, oaks, elms, the orange, rose, etc. It commenced among animals in Linguleæ (mollusks standing on a stem like a plant) and in crinoids and trilobites, if not earlier in the simple, systemless protozoans" (see EOZOON): "it ended in man. Sea-weeds were followed by ferns and other flowerless plants, and by gymnosperms, the lowest of flowering plants; these finally by the higher flowering species, the palms and angiosperms. Radiates, mollusks, and articulates of the Silurian afterwards had fishes associated with them: later, reptiles: later, birds and inferior mammals; later, higher mammals, as beasts of prey and cattle; lastly, man." "There were higher and lower species created through all the ages, but the successive populations were still, in their general range, of higher and higher grade; and thus the progress was ever upward." "With every new fauna and flora in the passing periods there was a fuller and higher exhibition of the kingdoms of life."

Admitting, then, this universal fact of progress in nature, some further propositions may be laid down as proven:

1. The method of progress has been, on the whole, from generalized types to those more special—*i. e.* with multiplication of organs and functions, or *differentiation*. Comprehensive types of earlier periods have sometimes been called by palæontologists "prophetic" types, containing elements which become distributed amongst those which succeed them. Examples of these are the following: *Ichthyosaurus*, comprising or combining the types of the fish and the reptile; *Pterodactyl*, *Archæopteryx*, and *Compsognathus*, those of reptile and bird; *Archegosaurus*, of amphibian and true reptile; *Sivatherium*, called in description a "pachydermoid antelope;" *Oreodon*, a "ruminating hog;" *Anoplotherium*, an "ornithoid, marsupialoid quadruped." All of these are *fossil*, and now extinct. Examples of an analogous kind are seen in a few animals of to-day, as *Ornithorhynchus*, a duck-billed quadruped; *Lepidosiren*, which combines some of the characters both of the reptile and the fish, etc. The molluscan group of cephalopods represents, in a manner, all four of the great types of Cuvier. "The beak, complex eye, tongue, ear, crop, gizzard, and cartilages analogous to the spine, point to the vertebrates; sucker-bearing arms and long axis, to radiates; cut off the mouth and its surroundings from the rest of the body, and we have the semblance of the star-fish: while the tentacles lead to the antennæ of the articulates." (*Ward, Descriptive Catalogue of Fossils*, etc.) Among plants, the fossil *Lycopodia* comprehend characters both of ferns and pines; *Cycads*, peculiarities of ferns, pines, and palms, etc.

2. *Unity of plan* pervades all organic nature, as exhibited in the *homology* or correspondence of parts which prevails throughout the animal and vegetable kingdoms. (See ANATOMY, and COMPARATIVE ANATOMY.)

3. Many *gradations* and *transitional forms* intervene between those great groups into which animals and plants are divided or classified. The comprehensive types above mentioned may be regarded as transitional. Such, too, are the Odontornithes (birds with teeth) and Ichthyornithes (fish-like birds), lately described by Marsh, and the Eobasileidæ and other tertiary forms between proboscidians and ungulates, described by Leidy, Marsh, and Cope. The last-named naturalist (*Evolution and its Consequences*, 1872) enumerates many genera in which, between the so-called species, there are determinable gradations; as of birds, *Corvus*, *Empidonax*, *Buteo*, *Falco;* reptiles, *Eutænia*, *Anolis*, *Lycodon*, *Naja*, *Caudisona*, *Elaps;* batrachians, *Rana*, *Hyla*, *Chorophilus*, *Barbourcartes*, *Amblystoma*, *Spelerpes;* fishes, *Ptychostomus*, *Pleurostomus*, *Salmo*, *Perca*, and others. A group of worms receives the name Gephyræa, because of its "bridging over" the gap between Vermes and Echinodermata. *Amphioxus* (lancelet) appears to connect vertebrates with the mollusca. Between *Polycistina* and *Spongia*, as Carpenter shows, comes *Acanthometrina*. Among fungous plants, especially those discerned by aid of the microscope, distinctions of a permanent kind are difficult to establish, and Kützing and Schleiden have asserted that "there are no *species*, but only *forms*, of Algæ."

4. A very remarkable correspondence prevails amongst animals and plants in *three orders of relative succession*: *a*, in geological time; *b*, in zoological rank; *c*, in embryological development. No naturalist has done more to establish the generality of this threefold correspondence than Agassiz, who, nevertheless, continues to oppose the hypothesis of evolution by transmutation or modification of specific types. What is meant by the above proposition is, that when one animal is known to be, *geologically*, more recent in its appearance on the globe than another somewhat allied to it, it will (generally) be found also to rank higher than it in the *zoological* scale, as measured by complication of structure, variety of powers, and, in some groups at least, greater intelligence; also, the more recent type passes, in its *embryological* development, through successive stages of change, including those of the less recent allied type, whose *adult* condition represents, more or less nearly, an *immature* or embryonic state of the higher and later, more advanced type. Some of the examples of this *parallelism* have long been familiar to naturalists; others have been but lately fully studied, especially by E. D. Cope in Salamandridæ (*Origin of Genera*, 1868) and Alpheus Hyatt in Cephalopoda (*Fossil Cephalopods*, etc., 1872). A few instances will answer our purpose. Trilobites, of the palæozoic era, resemble the embryonic state of *Limulus* of to-day. *Labyrinthodon*, of the trias, is like an arrested development of the later saurians. *Anoplotherium* recalls an embryonic stage of ruminants; the extinct dodo has been compared to an incompletely developed duck or goose; the siren manifests a similar relation to the lung-breathing batrachians. "Man presents in his earliest stages of embryonic growth a skeleton of cartilage, like that of the lamprey; also, five origins of the aorta and five slits on the neck, like the lamprey and the shark. Later, he has but four aortic origins, and a heart now divided into two chambers, like bony fishes; the optic lobes of his brain also having a very fish-like predominance in size. Three chambers of the heart and three aortic origins follow, presenting a condition permanent in the Batrachia; then two origins, with enlarged hemispheres of the brain, as in reptiles. Four heart-chambers, and one aortic root on each side, with slight development of the cerebellum, agree with the characters of the crocodiles, and immediately precede the special mammalian conditions—a single aortic root and the full development of the cerebellum. Later comes that of the cerebrum also in its higher mammalian and human traits." In all this succession and parallelism it is important to remember that the human embryo at no time assumes the *exact* or *entire* character of that of any other order of mammals, or that of reptile, bird, or fish. It is only *assimilated* to these lower types, without ever being identified with either of them. Yet this assimilation is a fact of very great importance.

5. *Teleology* is the name given to the study of another class of facts, coextensive with our acquaintance with nature, and especially obvious in the structures of the higher beings—viz., those which display *adaptation* and give evidence of purpose. These are most of all familiar in our own bodies, as the complex formation of the eye as an instrument of vision, with a nerve to convey the impression of light and a brain to perceive it, the hand for prehension, the mouth for speech, the foot for support and locomotion, the stomach for digestion, etc. Natural science furnishes no more beautiful and wonderful instances of such adaptation than those carefully studied and described by Darwin in the formation of many plants, so as to be fertilized by the interposition of insects which visit the flowers for their food. (*Darwin on the Fertilization of Orchids; Gray, How Plants Behave.*) Such facts, and thousands of others in nature proving adaptation, are too clear to be ignored, although speculative reasoning has introduced a question in regard to their origin or causation. The simple truth is, that design is to be inferred, as *purposive adaptation* adheres to the facts; *is itself a fact.*

6. *Modification according to surrounding conditions* occurs, to a limited extent, both in animals and plants. Some dependence upon conditions is inevitable. Thus, the earliest consolidation of the surface of the earth made it ready only for the simplest and lowest of plants. The animals of primitive periods were all aquatic. The first land-plants and land animals appeared on the earth in the Devonian age. The soil of the mesozoic period, almost certainly, would not have supported our vegetation, nor any vegetation capable of maintaining the now existing types of animal life. The atmosphere, the oceanic and inland waters, and all other terrene conditions have been different in the succeeding epochs. The mould of the field and forest of our day is the result of an immensely complex series of productions and decompositions going on through all ages since the azoic era. Each time, by its actions and reactions, prepares the way for the next. Man was, probably, *necessarily*, the last created animal, because the highest and most complicated, and thus requiring the latest and highest elaboration of terrestrial conditions.

But *modification* by changed conditions, acting upon ex-

isting types, appears only within limitations. In organisms of little motility a law may be enunciated that "extension occurs chiefly in the direction of least resistance, and increase of density in the direction of greatest resistance." It is proper to give some examples to illustrate "conditional action" on individuals and species in nature.

Fungi are said by some botanists to be very variable, according to the places and circumstances of their growth. With higher aquatic plants, some individuals of which may have their leaves out of and others in the water, the air pores or *stomata* are often on the under side in the former case, and on the upper side in the latter. Tendrils of climbing plants cease growing when finding nothing to clasp, but grow thick and strong after taking hold of a support. Shells of oysters are thicker on a wave-washed shore than where the water is always tranquil. Tadpoles develop into frogs in a few weeks when exposed to sunlight; in the dark, they may be kept as tadpoles for months. *Cysticercus*, a small animal parasite, when lodged in the liver or brain of a man, ox, or hog, becomes a hydatid surrounded by a watery tumor; in the intestinal canal, a tape-worm ten or twenty feet long. When the queen-bee of a hive is destroyed, the workers will select a neuter larva, and by placing it in a royal cell and feeding it with queen's food, convert it into a queen. Late observations (*Am. Naturalist*, May, 1873) make it appear that the sex of butterflies may be controlled by diminishing or increasing the supply of food to the caterpillars; short allowance promoting a preponderance of the male sex. Wallace found in the Malay Archipelago a marked influence of locality in the characteristics of Papilionidæ. Some moles have rudimentary eyes, as if they had lost them gradually by want of use; and the same may be said of blind fish in large caves. (See Amblyopsis.) Lewes (*Nature*, Mar. 27, 1873) mentions that, while the young of salamanders usually undergo their transformation in the water, *Salamandra atra*, living high upon mountains, is born completely formed. M. Baray has observed that frogs in the volcanic island of Guadaloupe go through the tadpole changes *in the egg*. Domestic ducks have the leg bones heavier; wild ones, those of the wings. Udders of cows in the domestic state are much larger than when wild. The drooping ears of several domestic animals follow the change from the wild condition. The heads of wild hogs, and those of the horses of steppes or pampas, are larger than those of the domesticated animals. *Artificial selection* and breeding cause great diversities in animals and plants. Of the latter, witness the double flowers and numberless varieties "created" by the horticulturists, and such changes as those from the wild to the cultivated cabbage, broccoli, and cauliflower. Ancon sheep and the Otter breed of cattle are merely extreme instances of the many effects of utilized and directed variations. English greyhounds taken to hunt on a high Mexican plateau, 9000 feet above the level of the ocean, failed for want of breath, but their offspring acquired a capacity to run as well there as elsewhere. *Acquired instincts* are familiar, yet remarkable; as the fear of man amongst wild birds and animals, those of a newly visited country being always "tame." Hounds of different breeds, pointers, setters, retrievers, require almost no training to fit them for their parts in hunting, yet no such proclivities belong to the dog in the wild state; they are undoubtedly transmitted by inheritance. While several generations must be required to make a breed or variety with such distinct endowments, yet variations are sometimes quite *suddenly established*. Darwin mentions this of the black-shouldered peacock, occurring in five distinct cases among those of the ordinary kind, and, in at least one case, to the extinction of the previously existing breed. The same authority (*Animals and Plants under Domestication*, vol. i.) states that "climate directly affects the skin and hair of cattle." Angora goats, of the same original stock as those of Europe, acquire a long silky fleece. Sheep and some other animals are subject to enormous fattening of the tail near the Cape of Good Hope. Other examples might be easily added.

7. *Conditions favorable to the support of particular species of plants and animals do not necessitate their existence.* Prof. Asa Gray (*On the Derivation of American Plants: Pop. Science Monthly*, Oct., 1872) illustrates this fact as follows: "When we see how Australian eucalyptus trees thrive upon the California coast, and how our redwoods flourish upon another continent; how the so-called wild oat (*Avena sterilis* of the Old World) has taken full possession of California; how that cattle and horses, introduced by the Spaniards, have spread as widely and made themselves as much at home on the plains of La Plata as those of Tartary; . . . when we consider how the indigenous flora of islands generally succumbs to the foreigners that come in the train of man, and that most weeds (*i. e.* the prepotent plants in open soil) of all temperate climates are not 'to the manor born,' but are self-invited intruders,—we must needs abandon the notion of any *primordial* and *absolute* adaptation of plants and animals to their habitat which may stand in lieu of explanation." While a few naturalists, as Mivart, and, in regard to races of mankind, Agassiz, have advocated the view that the same species may have originated independently in several localities, the weight of evidence seems to be largely in favor of the opinion that *each species* (if not every *genetic* group or type *has had but one origin*; all "representative" species, such as those nearly, sometimes quite, identical on the two sides of the Atlantic, or otherwise locally remote from each other, being really the same in stock, only more or less modified after divergence and permanent separation in place and circumstances.

8. *Certain types vary, through long periods, very little, under any circumstances.* Among domestic species the turkey and peacock are examples of considerable stability. Gould asserts of humming birds that, with many thousands of them passing through his hands, he has "never observed an instance of any variation which would lead to the supposition that it was the result of a union of two species." (*Introduction to Trochilidæ.*) Several "persistent types," through extremely long periods, are well known to geologists. *Lingula*, *Discina*, *Rhynconella*, *Crania* have continued from the Silurian age to the present time. Some palæozoic corals are yet building islands or reefs in the ocean. Genera of carboniferous plants, insects, and Arachnida closely resemble some of the sort to day. The *Araucaria* of the oolite has left cones scarcely distinguishable from those of the same genus now growing. *Pleracanthus*, a fish of the Devonian and carboniferous eras, was as similar to sharks now existing as they are to one another. Some triassic mammals were equally close in alliance to those of recent times. Carpenter and Wyville Thomson have proved that a cretaceous fauna exists now at the bottom of the ocean. Hence is to be inferred the propriety of the admission of Darwin: "I believe in no law of *necessary development*." Huxley also, who has especially studied these persistent types, emphatically declares that their existence must be recognized in any theory of evolution.

9. While progress has been the rule (as already shown) in the great changes of nature through geological time, evidence also exists of the *decline and extinction of types*. Says Dana: "Five hundred species of trilobite lived in the course of the palæozoic ages: afterwards there were none. Nine hundred species of the ammonite group existed in the mesozoic—not all at once, but, as in the case of the trilobites, in a succession of genera and species; the last then disappeared. There have been 150 species of the nautilus tribe in existence; now there are but two or three, and these are peculiar to the present age. Seven hundred species of ganoids have been found fossil; the tribe is now nearly extinct." Barrande has studied trilobites exhaustively; he remarks (*Trilobites*, par Joachim Barrande, à Prague et à Paris, 1871) upon the notable diminution of their size, as well as of the numbers of their genera and species, after a *maximum* in the second of the three periods of their history; also, that such an order of increase, culmination, and decline was observed in all quarters of the globe alike. The same naturalist has likewise examined in detail the history of ancient cephalopods (*Distribution des Cephalopodes dans les contrées Siluriennes*, 1870), and points out the occurrence of some simple forms, later than others which were more complex. Alpheus Hyatt has given attention to the same succession: and he, with some others, understands the fossil Cephalopoda to exhibit, as it were, the *biography* of a type, closely analogous, in all its changes, to that of an individual cephalopod. Opening with the straight *Orthoceras* of the Silurian, it advanced through the coiled and more complex ammonite of the Jurassic, and declined through half uncoiled forms of the cretaceous, to end in the straight baculite. Also, the ammonite family itself, beginning with the *Goniatites* of discoidal shape, passed through the compactly coiled and elaborate true ammonites, to decline through the half-coiled *Scaphites;* the last being the old age of the type. Other instances would probably be more familiarly known if the attention of naturalists was generally directed towards this class of facts.

10. *Rudimentary parts* furnish one of the strongest arguments in favor of the hypothesis of a genetic connection among all animals (including man); at least among all those belonging to the same great types. By rudiments, in anatomy, are meant organs or structures imperfectly developed, so as to be almost or entirely without functional use. Each of them represents in germ, as it were, in one animal (or plant) that which is perfect and useful in another type. Examples are as follows: In plants, incomplete petals, stamens, or pistils in a great many instances; notably, undeveloped pistils in the male florets of some Compositæ. Among animals, the minute and useless wings of certain beetles and other insects; teeth in the jaws of fœtal whalebone whales, which are toothless

when mature; teeth also in the front part of the upper jaw in the embryos of ruminant quadrupeds (as the ox) and of a few birds: the mammary teats of male mammals; two imperfect udders in cows; imperfect wings of the penguin and apteryx; the splint-bones of the horse; unused hinder toes of several quadrupeds; small limb-bones under the skin of serpents, and similar ones of the pelvis and hinder limbs of whales. Man has a number of clearly marked rudimentary parts. Such are the three small and useless motor muscles of the external ear; the platysma myoides of the neck, homologous with the useful panniculus carnosus of the horse and ox; the little fold or caruncle at the inner margin of the eye, representing the nictitating membrane of birds; the os coccygis at the lower end of the spinal column, in place of the tail of lower animals, and which at one time in the human fœtus is longer than the limbs; the vermiform appendix of the large intestine, which in man has no use, but in one marsupial is three times the length of its body. The "lanugo" or hairy covering of the human fœtus at the fifth month is supposed by Darwin to be a rudimentary appearance of the first hairy covering of other mammals. Some anatomists regard the whole outer ear in man as a mere rudiment of the movable external ears of quadrupeds. The last molar (wisdom) tooth has the character of incomplete development, especially among civilized races of men. For the existence of any of those which are certainly rudiments no rational "final cause" has ever been proposed. It is intelligible *only* upon the supposition of their being relics of a long past descent from a *common stock* with those species, genera, or larger groups which now present the same organs in perfect development and answering a useful purpose. Their gradual disappearance when their utility has ceased is not strange upon such a view. Paget has given an additional reason why that disappearance should not be sudden, in the facts of "complementary nutrition;" that is, as every part, by taking some material from the blood, makes it more exactly fitted to the nutrition of the rest, rudimentary organs may serve this purpose for a while, after their own direct functional action has ceased.

Different Theories of Evolution.—It is a popular error that "Darwinism" is a precise synonym of "the theory of development." Several distinct views have been held, agreeing merely as to the one belief, of a *genetic* relation between the present and the past in all parts of nature; which is what we mean by evolution. Thus, for the origin of diverse species amongst plants and animals there have been (though not altogether mutually exclusive) the following hypotheses: 1. Self-elevation by "appetency," or use and effort: Monboddo, Lamarck, and Cope. 2. Modification by the surrounding conditions of the "medium:" Geoffroy St.-Hilaire, Quatrefages, Draper, and Spencer. 3. Natural selection, under the struggle for existence, with spontaneous variability, causing the "survival of the fittest:" Darwin, Wallace, and Hæckel. 4. Derivation by "pre-ordained succession of organic forms," under an "innate tendency" or "internal force:" Owen and Mivart. 5. Evolution by "unconscious intelligence:" Morell, Laycock, Murphy. 6. Less defined, so far, as a distinct hypothesis, but clearly implied in the writings of Prof. Asa Gray, Dr. McCosh, Baden Powell, the Duke of Argyll, and others, is the view of orderly creation "by law," through the immanent action and direction of Divine Power, working by the purposive collocation and adjustment of natural causes or forces. This is not accurately described as a theory of "supernatural or miraculous *interference*." It should be designated, rather, as that of *creative evolution*.

Mivart, the Duke of Argyll, and others have abundantly shown that there is no antagonism whatever between the two ideas of creation and evolution. Excluding a very few atheists and positivists, the great controversy has been, of late years, upon the question whether a right interpretation of the facts should lead us to conclude that creative power was exerted *only at the beginning*, all afterwards being only the manifold progressive results of "natural laws" acting without traceable design; or that, instead, the *immanence* of Divine Power is everywhere shown by nature in forms and processes specially exhibiting design, in such a sense that, in the words of David Hume (*Dialogues concerning Natural Religion*, Part iv.), "the whole chorus of nature raises one hymn to the praise of its Creator."

Descent of Man.—Darwin gives the following conclusion in his work on this subject (1871): "The most ancient progenitors in the kingdom of the Vertebrata at which we are able to obtain an obscure glance apparently consisted of a group of marine animals resembling the larvæ of existing ascidians. These animals probably gave rise to a group of fishes as lowly organized as the lancelet; and from these the ganoids, and other fishes like the lepidosiren, must have been developed. From such a fish a very small advance would carry us on to the amphibians. We have seen that birds and reptiles were once intimately connected together; and the Monotremata now, in a slight degree, connect mammals with reptiles. But no one can at present say by what line of descent the three higher and related classes—namely, mammals, birds, and reptiles—were derived from either of the two lower vertebrate classes—namely, amphibians and fishes. In the class of mammals the steps are not difficult to conceive which led from the ancient Monotremata to the ancient marsupials, and from these to the early progenitors of the placental mammals. We may thus ascend to the Lemuridæ; and the interval is not wide from these to the Simiadæ. The Simiadæ then branched off into two great stems, the New World and Old World monkeys; and from the latter, at a remote period, man, the wonder and glory of the universe, proceeded." Wallace (*Essays on Natural Selection*, 1870) furnished, in anticipation of Darwin's work on that subject, what still remains to be the most effective reply to its arguments in favor of the sufficiency of the hypothesis of natural selection to explain the origin of man. Wallace shows that in several important respects the advances from the *simian* to the *human* type of organization are such as cannot be accounted for by any possible fitness for success in the struggle for existence—namely, the superiority of the human larynx for voice and musical expression, of man's foot for progression in the erect posture, of his hand for delicate touch and varied prehension, the greatly increased size and capacity of his brain, and the entire absence of hairy covering from his back and shoulders. Hence Wallace writes (*op. citat.*) as follows: "The inference I would draw from this class of phenomena is, that *a superior Intelligence has guided the development of man in a definite direction* and for a special purpose, just as man guides the development of many animal and vegetable forms." It need scarcely be remarked that this evidence, coming from one of the originators of the hypothesis of natural selection, has still further importance in suggesting that this "intelligent guidance in definite directions for special purposes," so obvious in the nature of man, who is best known to us, will be likely to be equally manifest elsewhere in the organic kingdom when our knowledge of all its parts becomes more complete.

Sexual selection, urged by Darwin to supplement his theory, falls short of its purpose in several ways—especially as a *general* hypothesis—because it requires considerable intelligence in all the animals which exercise it as a supposed means of advancement in beauty of form, color, etc.; and yet very remarkable developments of similar traits and endowments appear in invertebrated animals (*e. g.* butterflies and other brilliantly beautiful insects, and varied and elegant shells of mollusks), and in the high ornamentation of flowers and leaves in many plants. Another cumbrous rather than serviceable speculative addition of Darwin's to his general theory has been that of *pangenesis*. Something very much like it was suggested by Owen in 1849, in his treatise on parthenogenesis, but it is quite as incredible, if not as inconceivable, as the "monadology" of Leibnitz. (See PANGENESIS.)

Evolution of Mind and Consciousness.—On this topic Darwin (*Descent of Man* and *Expression in Man and Animals*) has written with much ability; and so, amongst others, also have Cope (*Evolution and its Consequences: Penn Monthly*, Aug., 1872) and Chauncey Wright (*North American Review*, April, 1873, on the "Evolution of Consciousness"). Some success has been undoubtedly reached by these authors in framing a conceivable hypothesis for the transition from the "rudimentary" mental faculties of brutes to those fully developed in the human mind. Conscience is thus traced back, by Darwin, to a germinal appearance in the higher animals, originated by conflicts between "permanent social instincts and affections" and "more transitory individual instincts and propensities." Yet there is obviously truth in the statement of Huxley, that between the mind of the highest anthropoid apes and that of man there is an "enormous gap"—a distance "practically infinite." Tyndall also is often quoted on this subject (*Address to Physical Section of British Association*, 1868) as follows: "The passage from the physics of the brain to the corresponding facts of consciousness is unthinkable. . . . Were our minds and senses so expanded, strengthened, and illuminated as to enable us to see and feel the very molecules of the brain; were we capable of following all their motions, all their groupings, all their electric discharges, if such there be; and were we intimately acquainted with the corresponding states of thought and feeling,—we should be as far as ever from the solution of the problem, 'How are these physical processes connected with the facts of consciousness?' The chasm between the two classes of phenomena would still remain intellectually impassable." Aristotle was impressed with a similar conviction more than two thousand years ago, when he wrote (*De Gen. Anim.* II., iii., 10) that *reason* has

nothing in common with the material elements of the body, but that it alone comes from without, and is divine: "Και περιεται δε τον νουν μονον θυραθεν επεισιεναι και θειον ειναι μονον." It does not need for us to determine here upon a precise theory of the nature of mind to enable us to see how these conclusions bear upon the supposition of the *spontaneous* evolution of mind from matter, as well as somewhat less directly upon that of the spontaneous ascent of the mind of the brutes up to that of man.

The probable method of evolution of instincts in animals, by "accumulated and transmitted experiences" (Darwin, Spencer), or as "lapsed intelligence" (G. H. Lewes), has been well studied of late by the authors quoted, and by Carpenter, Spalding, Wallace, and many others. (See INSTINCT.) Here also we have to stop, at last, at the yet unbridged gap between insensitive, unconscious matter and sensitive, impressible nerve substance, capable at first of reflex automatic action, and then, higher, of intelligence, impulse, and volition.

We are now prepared to approach a conclusion by attempting an answer to the question whether the facts giving strength to the hypothesis of evolution really eliminate the evidence of *design*, of special purposes, in nature; and whether, admitting "creation" in any sense, science compels us to remit it altogether to an inconceivably remote origin of the universe. For the following reasons, principally, we must unite with Carpenter, Dana, Agassiz, Henry, Sir John Herschel, Sir William Thomson, Asa Gray, and many other recent scientists of the highest class in denying absolutely the insufficiency of the proofs of design in nature; and also in refusing to admit the elimination of *special* creative action or direct modification of nature from all periods since the first origination of the universe.

1. As Whewell (*Indications of the Creator*) has pointed out, the nebular hypothesis is null without a creative act to produce the required "inequality of distribution" of cosmic matter in space. Haeckel (*Nat. History of Creation*, Berlin, 1868) admits that the hypothesis is weak on at least two points—the heat of the gaseous nebular mass, and its rotary motion. "Every attempt," he adds, "to explain these facts leads us inevitably to the untenable theory of an absolute beginning." We may avoid the contradiction herein involved by holding simply that what is *inevitable* must be pre-eminently a *tenable* conclusion. Herbert Spencer has also committed himself to a self-destructive process of reasoning in his "First Principles," as has been clearly shown by an American reviewer (*New Englander*, Jan., 1872, and Jan., 1873). The "instability of the homogeneous," on which Spencer builds large consequences, might, as that reviewer observes, account for chaos, but never for a universe. For *action* and *reaction* there must be heterogeneity, a plurality of factors. Traced backward, the principle of "uniformity of force" in physics must necessarily have been powerless to make any *beginning* whatever. Carried forward without designing *will-force* to modify them, natural cosmic forces tend always to *equilibration*, and consequent *dissolution*. The universe must thus become, as it has been said, "its own cemetery." Sir William Thomson asserts (*On Geological Dynamics*) that "as energy is being continually lost from the earth by conduction through the upper strata, the whole quantity of plutonic energy must have been greater in past times than in the present." Yet in organic nature there has been a constantly increasing complexity and exaltation of types —integration of matter with accumulation of force ("bottled sunshine" of some authors); and this under the "struggle for existence" against a steadily increasing resistance. As stated by Prof. Cope (*Method of Creation of Organic Types*, 1871), "While the amount of growth-force potential in adult living animals has varied very irregularly throughout the animal kingdom, there being large and small, simple and complex, in every division, it would seem to have accumulated, on the whole, with the rising scale of animal types." Mivart's special hypothesis of an "internal force" determinative of evolutionary changes in organisms is vague and unsatisfactory while detached from the "will-force" (Wallace) of an immanent Creative Power. The "unconscious intelligence" of Morell, Laycock, and J. J. Murphy is certainly an *unthinkable* phrase, a "pseudo-idea," when proposed as the designation of an active power in nature. The presumption against organic evolution, with *true ascent* of types, being in any sense the result of the action of mere *cosmic* forces, is of the same nature with that against perpetual motion; it contradicts the doctrine of the conservation or persistence of force. As Leifchild puts it (*Higher Ministry of Nature*, pp. 325, 327), the assertion that "No-will has evolved will" is as absurd as "ex nihilo aliquid."

2. *Variation* is necessary to the Darwinian or any other "non-teleological" theory; and no such theory accounts for variation. Darwin requires also almost *infinite* variability of plants and animals; but, so far from infinite, observation shows it to be confined within very narrow limits. The *non-fertility of hybrids* of two nearly allied species is a very important indication of the present fixedness of those limitations. Also, species do not pass, in any case, into each other. Palæontology and recent zoology and botany are declared by Agassiz, Barrande, Dawson, Gould, Balfour, and Thomson to establish this. Thus writes Sir William Thomson (*Nature*, Nov. 9, 1871): "In successive geological formations, although new species are constantly appearing, and there is abundant evidence of progressive change, no single case has yet been observed of one species passing through a series of inappreciable modifications into another." Embryology is regarded by Agassiz as affording concurrent testimony in regard to the essential diversity of types. In a lecture at Cambridge, Mass., Mar. 6, 1873, he used the following language: "No invertebrate animal has any structural relation to man whatever, while every member of his own type has an intimate structural relation with him. You may compare a quadruped in certain phases of its growth with the adult condition of some lower kinds of vertebrates, and be amazed at the resemblance; but you cannot carry the comparison over into the type of articulates, or into any other type of the animal kingdom based upon a different plan. Within each type the development has a character as distinct as the plan on which the type is built. An insect, for instance, can never at any time of its development, after it has passed out of that universal condition of the ovarian egg to which I alluded, be compared to an oyster or a fish, but it passes through phases where it can hardly be distinguished from a worm; that is, in the course of its development it bears a transient likeness to the adult condition of a being standing lower in the type of articulates to which they both belong. In short, every animal belonging to any one of the higher groups, during the transformations by which he reaches the adult state, may pass through modified conditions, in each of which he resembles some being of his own type of the animal kingdom for whom that condition is final."

3. Were variation infinite, without the *regulation* of selective or directive design, a simple calculation of probabilities (see "North British Review," June, 1867) shows that a merely chaotic complication of forms must result, the "struggle for existence" notwithstanding.

4. Infinite time has been proposed as affording a solution of the difficulties of natural selection. But infinite time would not alter the nature of the necessary result of infinite variations, nor would it regulate finite ones. Further, Sir William Thomson, Croll, and Gould have shown, from various *data*, that so far from infinite time, not more than one hundred millions of years can have been the duration of the present relation of our planet to the sun—a period quite too short (were *any* duration of time sufficient) for the genesis of organic nature merely by spontaneous modification and natural selection.

5. Without design (as Mivart has shown) *incipient* structures, which become useful only when completely developed, have no explanation at all. Further *items* of fact unexplained, apart from teleology, are—the opposition of the *sexes* in plants and animals; the *metamorphoses* of insects; the cessation of the individual life; and the renewal of life-progress by parental reproduction. Moreover, as to the origin of a *new species*, whose relation to an earlier allied species is supposed to be similar to the connection between the different stages of the life of one individual, we have the *fact* of individual reproduction exemplified under our knowledge; but what corresponds, in the birth of a *new type*, to the sexual reproduction of a new individual, especially in the case of the *first* created type?

Accepting, then, with Herbert Spencer, the evidence found everywhere of the unity of the "inscrutable universal Power" which is the Cause of nature, there is proof, also, in the multiplicity and adjustment of the manifestations of that Power, that it has the attributes of Intelligence and Will. Every *specialization*, each true *elevation* of type (which is a different thing from modification on the same plane of being), involves new force-expenditure. Certain *factors* have been *added* in the evolution of nature whose origin is a "mystery" as yet quite unsolved by science. It is rational and philosophical, therefore, in the absence of any solution by secondary causation, to refer them, provisionally at least, to the direct creative action (whether sudden or gradual we cannot know) of the First Cause. Such "factors," superadded from time to time in the past history of our globe, have been —1. life; 2. animality, as distinct from vegetative life; 3. mind-force, instinct, intelligence, ψυχη; 4, πνευμα or spirit (see 1 Cor. xv. 46), possessed by man alone of all creatures on the earth. While *Theism* must rest essentially upon evidence other and higher than that of physical science, it would appear that the facts of evolution tend to confirm and strengthen that evidence. "If there

has been an evolution," writes Canon Kingsley, "there must be an Evolver." "Let us hope," says Prof. Gray (*Address before Am. Associa. for Adv. Science*, 1872), "that the religious faith which survived, without a shock, the notion of the fixity of the earth itself, may equally outlast the notion of the absolute fixity of the species which inhabit it—that in the future, even more than in the past, faith in an *order*, which is the basis of science, will not (as it cannot reasonably) be dissevered from faith in an *Ordainer*, which is the basis of religion." We find development in the succession of divine dispensations described in the Old and New Testaments—of the patriarchs, of Moses, the judges, prophets, and kings in the Old, and of Christ in the New Covenant. "The law made nothing perfect, but the bringing in of a better hope did." (Heb. vii. 19.)

Evolution in Human History—Dr. McCosh has referred (*Christianity and Positivism*, 1872) to some phases of the progress of mankind, of which three stages are distinguishable—the era of the *predominance of physical force*, that of *intellectual supremacy*, and that (hardly culminated as yet) of *moral and spiritual power*.

As a question in archæology, it has been often argued whether man was originally savage (Tylor, Lubbock, Darwin), and thence self-elevated into civilization, or was at the beginning (Whately) supernaturally gifted with such knowledge as prepared him for refined life and culture, afterwards, in many places, to be lost and regained, again and again, through the ages. Neither of these alternatives compels our entire or exclusive assent. Probably man was at first infantile or puerile, both in innocency and ignorance. (See "Primeval Man," by the Duke of Argyll.) Normally in communion with his Maker, his destination was to continue morally pure and to advance in mental culture. History shows, instead, barbaric degeneration to have been the rule before the Christian era, with partial renewals and expansions of civilization in certain localities at different times. There is no proven instance of any nation or race having initiated its own advancement out of barbarism, while there are many examples of the deterioration of powerful empires and centres of magnificent culture into the savage or almost savage state. Always *a force from without* has begun the elevation of a race or community. Where history has failed to reach such beginnings, tradition follows its clues towards them, and always with the same indication—Egypt from India, Greece by Cadmus, Rome from Greece, Europe first from Rome, and afterwards from Palestine.

If India and China furnish no clear traces of such foreign origins of their advancement, what does this amount to? In the one instance, an old culture vanishing away; in the other, petrifaction into a half civilization, ceasing, many centuries since, to make further progress. After Greece and Rome had exemplified and fallen from the very culmination of intellectual and imperial development, the world (it may be believed) would have totally degenerated into a more than mediæval darkness but for the coming of a "force from above" in the advent of Christianity. By it, as now known in Europe and America, has been made possible and actual, for the first time in the world's history, a *continuously progressive civilization*.

We may conclude this article by a brief general statement upon the whole subject of development: "The only idea of creation which is at all *conceivable* is creation by a process, the steps of which have a succession, which, if known, would be rationally comprehensible." So regarded, evolution or development is the only expression according to which any consistent statement of the facts of nature can be made. But evolution is not a force, cause, or "law." It is a summary term for the general mode of succession of the complex results of *all* natural forces and laws under the Divine government.

HENRY HARTSHORNE.

Evolu'tions, Mil'itary, the movements by which troops change the order, position, and direction of their primary formation. All such movements as marching, countermarching, changing front, forming line, facing, wheeling, defiling, deploying, etc., come under the general head of evolutions. All evolutions are performed according to a regulated system, which differs in its details in the armies of different nations.

Ev'ora (anc. *Ebora* and *Liberalitas Julia*), a town of Portugal, capital of the province of Alemtejo, is pleasantly situated about 73 miles by rail E. by S. from Lisbon. It has two ruined forts, a large Gothic cathedral founded in 1186, several convents, and a library of about 50,000 volumes. It has been an archbishop's see since 1541. Here are manufactures of ironware and leather. Ebora was taken by Sertorius about 80 B.C. Here are Roman antiquities which are more interesting than any others in Portugal. Among them are an aqueduct said to have been built by Sertorius; a temple of Diana with beautiful Corinthian columns; and a brick tower adorned with columns of the Ionic order. Pop. 11,965.

Évremond (CHARLES DE SAINT-DÉNIS), seigneur de Saint Évremond, a French courtier and *littérateur*, born near Coutances, in Normandy, April 1, 1613. He was witty and accomplished, a perfect specimen of an Epicurean of that time, squandering his life in the pursuit of frivolous pleasures, but ready to give it up at any moment for the sake of a bon-mot. He entered the army about 1629, and became a friend of Turenne and the prince of Condé. Having given offence to Louis XIV. by his raillery and sarcastic wit, he took refuge in England in 1662. He gained the favor of Charles II., who granted him a pension of £300, and he never returned to France. He wrote dramas, essays, and letters, of which his "Comedie des Academistes pour la Reformation de la Langue Francois" is an exceedingly witty, elegant, and entertaining production. His "Sir Politics," which he made in company with Buckingham, is very weak. Died in Sept., 1703.

Évreux, à'VRUH' (anc. *Mediolanum*, afterwards *Eburovices*), a city of France, capital of the department of Eure, is pleasantly situated on the Iton about 67 miles by rail W. N. W. of Paris, with which it is connected by railway. It is a bishop's see, and has a fine old cathedral, an episcopal palace, a theatre, a clock-tower built in 1417, and a botanic garden. Here are manufactures of cotton and woollen fabrics, leather, etc. Évreux has sustained numerous sieges. It was taken and pillaged by Rollo the Norman in 892 A. D., and was burned by Henry I. of England in 1119. Pop. 12,320.

Evron, a town of France, in the department of Mayenne. Here is an ancient Benedictine abbey. The chief manufacture is table linen. Pop. 5243.

Ew'ald (JOHANNES), a Danish poet, was born in Copenhagen in 1743. In his early youth he lost his father, who was a minister, and soon after, yielding to the fantastic impulses of his nature, he gave up his studies and enlisted in the Prussian army. He felt very disappointed, however, as people of his character always do when they meet the reality. He deserted and joined the Austrians. But they did not satisfy him either. He deserted a second time, and returned to Copenhagen, where he spent the rest of his life as a literary man. He died in 1781 in utter poverty and degradation: he was a drunkard. In his literary business, however, Ewald was very industrious and conscientious. All his works bear evidence of great study, deep meditation, and untiring labor; there is no rashness, no halfness about them. He did the very best he could. Yet his writings—with the exception of some few genuine pearls among his songs, as "King Christian," which became the national hymn of the Danes, "Liden Gunver," "Rungsted's Lyksalighed," etc., and his essay "On Bachelors," which is a specimen of the most elegant humor—are marked with the same empty enthusiasm and fantastic excitement as was his life. The innermost kernel of his tragedies "Adam and Eve" and "Balder's Death" is vapor. To a sound taste they are tiresome and unpleasant. They are interesting only as historical documents to the scholar who does not consider them from a merely artistic point of view, but looks at them in their connection with the period in which they were produced. Holberg had taught the Danish people how to read. He had made them eager after books. Through his influence it had become as necessary for them to have a literature as to keep an army. But he had not taught them how to write. He had left them as types no models which could be used; and it took two generations before he came who did—Adam Oehlenläger. Meanwhile, the public arranged itself into two camps—one, "The Norwegian Club," importing French forms and French tastes; and the other, "The Danish Society," importing German ideas and German principles. Klopstock lived at that time at the Danish court, from which he had a pension, and Ewald, who was his admirer, and who in the Danish literature represents the same ideas, though not the same influence as Klopstock in the German, became the hero of "The Danish Society." A fearful battle issued between these two parties—noise and smoke, rattling and booming, as from the fight of two hostile armies. What was said during the evening in the club or in the society became the topic of conversation next day all over the country, from the drawing-room to the barber-shop, and fifty years later old men would still tell with pride how they had been present when this or that epigram was first recited or this or that song first sung. Fearful also was the result of the battle, for in artistic respects it was next to nothing.

Among all which the Danish literature produced between Holberg and Oehlenläger that which is good can be read in one short hour, and no great harm would be done if it

were forgotten in the next. But by studying the period in its details, it is possible to show how all the mental powers of the nation then awakened, and how they sought and found the same course, until at last, through Oehlenläger, they broke forth in one broad, glittering stream, useful to the world; and in this study every line of Ewald is interesting and important. CLEMENS PETERSEN.

E'wald, von (GEORG HEINRICH AUGUST), a celebrated German Orientalist and biblical critic, born at Göttingen Nov. 16, 1803. He became in 1831 professor of philosophy in the University of Göttingen, and he obtained the chair of Oriental languages in 1835. In 1837 he was removed on account of his liberal political opinions; he and five other professors, among whom were Gervinus and Grimm, solemnly protesting against the abolition of the free constitution which the Hanoverian king had felt himself compelled to give during the revolutionary commotions in 1830. Ewald went to Tübingen as professor in theology in 1838, but his position here was not very pleasant, as he had to defend himself against the attacks and intrigues both of the Roman Catholic party and the Hegelians. He was reinstated in his chair at Göttingen in 1848, and was elected a member of the North German Parliament in 1869. Among his numerous works are a "Hebrew Grammar" (8th ed. 1870), "The Poetical Books of the Old Testament" (4 vols., 1835–37), a "History of the People of Israel until the Advent of Christ" ("Geschichte des Volkes Israel bis auf Christus," 7 vols., 3d ed. 1864–69), "The History of Christ and his Time" (1857), and "The History of the Apostolic Age" (1858). In 1848 he founded at Göttingen "The Year-Book of Biblical Science" ("Jahrbuch der Biblischen Wissenchaft"). About the influence which he exercised on the theological study of the Bible there may be different opinions, but his contributions to a better understanding of the language of the Old Testament are of undoubted value. Died May, 1875.

Ew'bank (THOMAS), a writer on mechanics, was born in the county of Durham, England, Mar. 11, 1792. He emigrated to New York in his youth, and was appointed commissioner of patents by the President of the U. S. in 1849. He published, besides other works, a "Descriptive and Historical Account of Hydraulic and other Machines, Ancient and Modern" (1842), and "Thoughts on Matter and Force" (1858). Died Sept. 16, 1870.

Ew'ell (BENJAMIN S.), LL.D., an American officer and educator, born in 1810 in the District of Columbia, graduated at West Point in 1832, served while lieutenant of artillery as assistant professor at the Military Academy, till he resigned, Sept. 30, 1836; civil engineer (1836–39), professor of mathematics at Hampden-Sidney College, Va. (1839–42), and of mathematics and natural philosophy (1842–46), professor of mathematics and military science in Washington College, Va. (1846–48), professor of mathematics and acting president of William and Mary College, Va. (1848–49), professor of mathematics and natural sciences (1849–61), and president of William and Mary College (1854–61) and since the civil war. GEORGE W. CULLUM, *U. S. Army.*

Ewell (RICHARD STODDARD), GENERAL, born Oct., 1816, in the District of Columbia, graduated at West Point in 1840, served on the Western frontier (1840–45), on coast survey (1846), in the war with Mexico (1846–48), engaged at Vera Cruz, Cerro Gordo, Contreras, Churubusco, Molino del Rey, and Chapultepec; became captain of dragoons in 1849, and did frontier duty in New Mexico (1850–61), and engaged on the Gila and Pinal Apache expeditions (1857 and 1859), encountering the Apaches on the Gila River in a skirmish. Resigning May 7, 1861, from the U. S. army, he joined the Southern forces in the civil war, serving in the Manassas campaign (1861), engaged at Blackburn's Ford and Bull Run (1862), engaged at White Oak Swamp and Cedar Mountain, defeated at Kettle Run, and engaged at Manassas (1862), in the Maryland campaign (1862), in which he was severely wounded; became lieutenant-general in 1863, and succeeded Stonewall Jackson at his request, being in command of Second Corps at Winchester, Gettysburg, Wilderness, and subsequent operations of the campaign; and was captured April 6, 1865, at Sailor's Creek. He was a bold, blunt, honest soldier, and on the collapse of the Southern Confederacy accepted in good faith its results. Died Jan. 25, 1872, near Spring Hill, Tenn.
GEORGE W. CULLUM, *U. S. Army.*

Ew'ing, a post-village in Franklin co., Ill., 8 miles N. E. of Benton, noted for its large woollen-factory, and as the seat of Ewing College, a flourishing institution.
J. S. BARR, PUB. "BENTON STANDARD."

Ewing, a township of Mercer co., N. J. Pop. 2477.

Ewing, a post-village of Washington township, Hocking co., O. Pop. 50.

Ewing (CHARLES), LL.D., born in Burlington co., N. J., July 8, 1780, graduated at Princeton in 1798, was called to the bar in 1802, practised at Trenton, and was chief-justice of New Jersey 1824–32. Died Aug. 5, 1832.

Ewing (Rev. FINIS), one of the fathers of the Cumberland Presbyterian Church, was born in Bedford co., Va., July 10, 1773, of Scotch-Irish stock, and is said to have studied for a time in college. He removed to a place near Nashville, Tenn., and in 1823 married a daughter of Gen. William Davidson, joined a Presbyterian church, and soon after removed to Kentucky. Awakened in 1800 to a new religious life, he was licensed to preach, and in 1803 was ordained by the Cumberland Presbytery. His ordination not being recognized by the Kentucky synod, the presbytery being dissolved, and the action of the synod being sustained by the General Assembly, he with two others in 1810 formed the germ of the new Cumberland Presbyterian Church. In 1820 he removed to Missouri. Died at Lexington, Mo., July 4, 1841.

Ewing (JOHN), D. D., an American Presbyterian minister, born in Nottingham, Md., June 22, 1732. He became pastor of the First Presbyterian church of Philadelphia in 1759, and provost of the University of Pennsylvania in 1779. Died in Sept., 1802.

Ewing (THOMAS), LL.D., a statesman, was born in Ohio co., Va., Dec. 28, 1789. In 1792 he removed with his parents to Ohio. In his youth he prepared himself for college by night study while employed in the Kanawha salt-works. In 1815 he graduated at Ohio University at Athens, receiving the first degree of A. B. ever conferred in that State. He was called to the bar in 1816, and was U. S. Senator from Ohio (1831–37 and 1850–51), U. S. secretary of the treasury (1841) under Harrison, and secretary of the interior under Taylor (1849). He was the father of Gen. Thomas Ewing and father-in-law of Gen. W. T. Sherman. Died Oct. 26, 1871.

Ewing (THOMAS, JR.), a son of the foregoing, was born at Lancaster, O., Aug. 7, 1829, was educated at Brown University, was private secretary of President Taylor (1849–50) studied law at Cincinnati, removed in 1856 to Leavenworth, Kan., was chief-justice of Kansas (1861–62), colonel of the Eleventh Kansas Volunteers, 1862, served with distinction in the civil war, chiefly in Missouri and Arkansas, becoming a brigadier-general of volunteers in 1863, and major-general by brevet in 1864. Since the war he has been a lawyer in Washington, D. C.

Ew'ington, a post-village of Huntingdon township, Gallia co., O. Pop. 191.

Ex'actions [from Lat. *exactiones, tallice*] was a legal term of ecclesiastical jurisprudence, used in the Middle Ages to denote such duties or contributions, demanded by the clergy of their parishioners, as were extraordinary, either because they were new and against custom, or because their amount was unduly increased. They were illicit, and it was found necessary repeatedly to denounce their unlawfulness. The power of the clergy over their parishioners, or of the bishops over the subordinate clergy, was so great that it was easy for them to make the most outrageous exactions. In 589 the third Council of Toledo forbade the bishops "exactiones diocesi vel damna infligare;" and the meaning of this is more exactly defined by Leo IV., who in 853 forbade the bishops to exact from the clergy and ecclesiastical institutions of their dioceses "dationes ultra statuta patrum aut super appositæ in angariis." Yet, in 1179, Alexander III. found it necessary to repeat: "Prohibemus ne ab abbatibus, vel episcopis, aliisve prælatis novi census imponantur ecclesiis, nec veteres augeantur, nec partem reditnum suis usibus appropriare præsumant."

Exarch [Gr. ἔξαρχος, a "leader"] was in ancient Greece the title given to him who conducted the dramatic chorus during the performance, as distinguished from the coryphæus and the choregos; the former of which titles denoted the teacher of the chorus, him who taught them the songs and dances, which office generally was filled by the author of the play; while the latter title, that of choregos, simply was given to some rich citizen who supplied the costs of the outfit of the chorus.

Later on the title was used in the Eastern Church to denote the highest ecclesiastical dignity, and was bestowed on the bishops of Alexandria, Antioch, Ephesus, Cæsarea, and Constantinople, but was soon exchanged in most places for that of patriarch, though it never was wholly abolished. At present it denotes a chancellor or deputy under the patriarch in the Russian Greek Church. He travels as a delegate from the patriarch through the diocese, investigating the discipline of the monasteries and the observance of the canons, and forming a kind of court of appeals in all ecclesiastical cases arising between the clergy and the people.

Ex'archate, the title of exarch was, for some time, ap-

plied also to civil dignitaries of the highest rank—to the viceroys who ruled over those border provinces of the Byzantine empire which were most exposed to the danger of being invaded by the barbarians. Thus, an exarchate was established in Africa in 534, and existed till 698, when it was finally overthrown by the Arabian conquest. The most important of these exarchates, however, was that established in Italy in the time of Justinian I. by Narses. In 552, Narses, who originally was a eunuch belonging to the household of Justinian, but who turned out a military commander and statesman of great talent, led an army consisting of Lombards, Huns, Heruli, Armenians, and Persians—which incongruous mass he swayed with indomitable power—along the coasts of the Adriatic, until he, S. of Ravenna, crossed the Apennines and met the Goths at Tagina, where he totally defeated them; their king Totila fell in the battle. Narses now took Rome, and the end of the Ostrogothic empire in Italy was at hand. Teias, the successor of Totila, was defeated and slain in a battle at the banks of the Sarno, near Naples, which lasted two days, and Narses immediately commenced the organization of Italy as a province of the Byzantine empire. He had to fight once more, however. New swarms of barbarians, mostly consisting of Franks and Alemanni, poured down the Alps and spread devastation before them wherever they came. Narses waited for some time, but when he saw that the luxurious and riotous life to which Italy induced them had thoroughly demoralized them, he attacked them at Casilinum in Campania, and hardly 5000 out of 75,000 escaped from the massacre. From this time (554–567) Narses ruled Italy as a province of the Byzantine empire, under the title of exarch, and with full civil, military, and judicial authority. After his death, in 567, followed Flavius Longinus, and the Roman exarchate continued to exist, though with various fortunes, till 752. The exarchs placed *duces* (dukes) at the head of the administration of the different provinces, but the dukes of Venice and Naples soon made themselves independent. So did the bishop of Rome, Gregory II., and the dominion of the exarchs, by degrees, dwindled down to a very limited extension, comprising only a few provinces of Central Italy around the city of Ravenna, which was their residence. The last exarch was Eutychius. In 752, Aistulf, king of the Lombards, conquered Ravenna, but in 755 he had to give most of the possessions of the exarchate to the see of Rome, compelled to do so by Pepin the Little. The title of exarch was used, however, in Western Europe as a civil and military title till the middle of the twelfth century. CLEMENS PETERSEN.

Exauvilliez (PHILIPPE-IRÉNÉT BOISTEL D'), a French author, was born at Amiens Dec. 6, 1786. In 1815 he lost the greater part of his fortune, and went to seek some employment. Having failed to secure any, he turned to literature, and wrote a great number of religious and moral sketches and pamphlets, which were not without effect. His essay, "Le Bibliothéque de Saint-Gervais," 1831, gave the first impulse to the establishment of small libraries all over France, which have proved of great benefit to the general elevation of the people. Exceedingly curious is his translation of Walter Scott's novels (1840), from which he blotted out every passage which in any way could be interpreted as telling against the Roman Catholic religion, and also all love-passages as far as possible. He was editor of the "Journal des Personnes pieuses." Died in 1858.

Excam'bion [from the It. *cam'bio*, "exchange"], in Scotland, is the legal name for an exchange of lands, or the contract by which one piece of land is exchanged for another. Heirs possessing under deeds of entail are empowered to exchange or excamb certain portions of the entailed lands.

Ex Cathedrâ, a Latin phrase originally applied to decisions given by popes or prelates from their *cathedrâ* (chair), *i. e.* in a solemn judicial manner. Hence it is applied to every decision pronounced by any one in the exercise of his proper authority, as a judge on the bench, etc.

Ex'cellency [Lat. *excellen'tia*, from *excello*, to "excel"], a title of honor which was borne successively by the mediæval Lombard kings, by several emperors of the West, and by other Italian potentates. It is now given to ambassadors, governors of British colonies, and the governor of Massachusetts. The President of the U. S. and the governors of many of the States have the same title by courtesy.

Excelmans, or **Exelmans** (REMI JOSEPH ISIDORE), BARON, a French marshal, born at Bar-le-duc Nov. 13, 1775. He entered the army in 1791, and became aide-de-camp to Murat in 1801. He served with distinction at Austerlitz (1805), and gained the rank of general of brigade for his conduct at Eylau (1807). In the Russian campaign (1812) he commanded a division, and gave proof of much skill. He directed a corps at the battle of Waterloo (1815), after which he passed four years in exile. He was restored to his title as a peer in 1831, and became a marshal of France in 1851. Died July, 1852.

Excel'sior [the comparative degree of the Lat. *excel'eus*, "high," "elevated"] signifies "higher." It is the motto of the State of New York.

Excelsior, a post-township of Hennepin co., Minn. Pop. 335.

Excelsior, a township of Sauk co., Wis. Pop. 874.

Exchange, in commerce, is a term of various application—to places of rendezvous of merchants, bankers, and tradesmen; to the stock-markets and to markets generally; and to the financial relations existing between different markets, domestic or foreign, as indicated by the difference of value in their respective currencies. "In every department of human affairs," says John Stuart Mill ("Pol. Ec.," vol. i.), "practice long precedes science; systematic inquiry into the modes of action of the powers of nature is the tardy product of a long course of efforts to use those powers for practical ends." Thus, society consists of an immense mass of practice, not yet reduced to scientific order. It is only within a comparatively short period that even the most advanced nations have become sufficiently enlightened to contemplate the possibility of their existence without the necessity of a vast organization of physical forces for mutual defence or assault. Happily, this very necessity has set in motion and developed the more beneficent applications of those forces, and converted the military power itself, measurably, into an auxiliary of commercial interests. And so great has been the energy of the people, so numerous their inventions, and so rapid the growth of society in modern times, that the scientific principles of organization have been, so to speak, clogged by the accumulation of physical affairs under the spur of immediate necessity. The vast increase in the number and variety of transactions in all parts of the civilized world has outstripped the knowledge of law, and its application to the correction of disorders by which the labor of all countries is oppressed, yielding neither to the producer nor to the capitalist a certain and satisfactory reward for his exertions, excepting in solitary instances. The effect of this state of things, in which law ceases to be recognized as having any connection with practical affairs, cannot be otherwise than disastrous; and it is from the very midst of disasters which press from every quarter that the first steps are taken towards scientific organization. It is in strict accordance with these natural principles of development that the commercial exchange or rendezvous of merchants and dealers has been organized in all large cities of active trading countries. Hence, there is a *stock-brokers' exchange*, where, whatever abuses exist, there is a severe inquest maintained concerning the validity of investments and the real value for income of all public and corporate securities in the shape of stocks and bonds. Before any new securities are allowed to be quoted or sold on the exchange they are subjected to rigid examination by a committee. A system of arbitration supersedes all appeals to the law for the settlement of disputes. The denunciations which are frequently heard of the "board of brokers," and of its "gambling transactions," are mostly by ignorant people who know nothing whatever of the character and objects of the association. The general influence of it is favorable to fair and upright dealing. But for the supervision that it maintains over the innumerable shapes of investment which are thrown upon the market there would scarcely be any effective bar to imposition and fraud. What the stock exchange is to financial securities, the *produce exchange* is to the staples of food. It maintains inspection of all articles to prevent adulterations, classifies them, and adopts marks or brands whereby they become known in the markets of all countries. It recognizes superior qualities, establishes grades, and takes cognizance of methods of preparation for export to foreign markets, by which the general facilities of commerce are improved and great economies secured. So advantageous have these inspections and precautions proved that every important branch of business has come to be represented by its exchange. There is a *cotton exchange* in all ports and cities where that staple has its entrepôt. Likewise, there is a *mechanics' exchange* and a *real-estate exchange* in almost every considerable town in the U. S. In some places all branches of business are embraced by the same association, each having its department, with bureaus of record and information, and committees to arbitrate differences, whereby vexatious and expensive litigation is prevented. One of the most commodious and remarkable exchanges in the world is that of Hamburg, Germany. Besides the usual bureaus representing every important branch of business, it has a library of near 50,000 volumes relating to subjects of commercial interest in all parts of the world, and also

a valuable collection of maps and charts of all seas and coasts. No traveller stops at Hamburg without visiting the Exchange, to which admission is granted by having his name inscribed on the books through the introduction of a member. The great hall is surrounded by spacious galleries, from which the movements of the crowd on the main floor may be observed. The acoustic properties of this hall are such as to produce the most extraordinary reverberations of sound, resembling at first, when the members begin to congregate, a noise like that of a small cataract. As the crowd increases it gains depth and volume, until at "high 'change" the roar is an exact counterpart of a stupendous fall and rush of waters, in which all inferior sounds are swallowed up. As there is no distinct source to which the immense reverberation of sound can be traced, the visitor looks about in amazement to discover its origin. Notwithstanding the roar, personal conversation is carried on even in the most moderate tones without the slightest inconvenience.

Bills of Exchange.—Exchange as a method of commercial settlement is probably of nearly coincident date with the origin of commerce. De Paw says that bills of exchange were used at Athens, and were known among the Arabs. The Abbé Raynal says they were known in the East Indies when the Portuguese first arrived there. Macpherson says there is no express mention of them in any known record until the beginning of the thirteenth century, when the pope, in the plenitude of his power as sovereign of the world, offered the kingdom of Sicily and Apulia to King Henry III. on the condition that he would drive Manfred out of it. Henry accepted it for his second son, and authorized the pope to carry on the war against Manfred at the expense of England; whereupon the pope took up large sums from the Italian merchants, who were compensated by drawing bills on the English prelates, and sending agents to collect them. Owing to the balance of trade or debt between any two places, either domestic or foreign, there may be a difference of value between a given quantity of gold or silver in such places respectively. This difference is called the exchange, and it is generally expressed by a percentage on the bill that is bought for remittance. The exchange is said to be at *par* when there is no such difference, or "when a given quantity of gold in one country is convertible at the market-price into such an amount of the currency of that country as will purchase a bill of exchange on the other country for such an amount of the currency of that other country as will there be convertible at the market-price into an equal quantity of gold of the same fineness." Exchange is said to be in favor of a country when a given quantity of gold purchased in it is convertible into such an amount of the currency of another country as will there be convertible into a *greater* quantity of gold of the same fineness; and it is said to be adverse, or against a country, when the proceeds of a bill of exchange will yield in the country to which it is transmitted a *smaller* quantity of gold of the same fineness. The effective limitation, therefore, to the price of a bill of exchange designed for transmission to another country is the cost of sending gold. The exchange will ordinarily rise to the height of the cost of transmitting gold, which is made up of freight, insurance, interest, and brokerage; but if there is little gold in a country, and if the sources of supply are uncertain, it may greatly exceed that cost, especially if the balance of foreign debt be adverse. The principal circumstance which determines the cost of gold in a country is the state of its foreign account. If its exports are continuously less than its imports, it must transmit gold or silver to pay the difference. It is assumed by some writers that the state of the domestic currency exerts an influence on the price of exchange; but if so, it must be by secondary action, either by favoring the amount of imports, or by such derangement of productive labors as will reduce the exports. Whatever incidental conditions may transiently affect the state of debt between two countries, as the waiving of a present demand for payment or the immaturity of debt, it still returns to this: What is the state of the foreign debt? Every other term may be laid aside to get a clear understanding of the meaning of exchange, which thus becomes perfectly simple and intelligible. The masterly financial system of England practically gives to the U. S. but one foreign creditor to deal with. England is the agent of all foreign markets. Whatever debt may exist between the U. S. and France, Germany, or Brazil, is compounded in the rate of exchange between England and the U. S. The interest on the national debt of the U. S. held in foreign countries is roundly stated at $100,000,000 a year. In addition to this, there is the balance of commercial debt, which has generally been adverse, with exceptional years of short harvests in Europe, when American breadstuffs have come into active demand. Besides the yearly drain of $100,000,000 of gold to pay the interest on our debt held abroad, an eccentric element enters into the rate of exchange between the U. S. and other countries through our domestic financial policy. It is foreign commerce, and foreign commerce exclusively, that governs the flow of the precious metals from one country to another. These having been adopted by all nations as the common medium of liquidation, they should be held inseparable from that function. It is a violation of agreement for a government to abstract and hold estranged from use any part of this common medium; and moreover, it is an act of commercial injustice to the weaker markets, which may thence be forced on financial pressure and disorders destructive to their trade and industry. Since the year 1846 the government of the U. S. by its financial policy has held in positive and complete abstraction from all use many millions of the precious metals, whereby not only have all markets in common suffered injury, but especially the domestic market through the effect of this policy on the foreign exchange, both directly in controlling its price, and indirectly by the discouragement of productive labors and the depression of the export trade. Thus, the rate of the foreign exchange for near thirty years past has been continuously subject to the adverse action exerted by a complete separation of our treasury balances from their legitimate function in the scales of commerce. Those balances have varied from a minimum of $25,000,000 to a maximum which has ranged from $80,000,000 to over $100,000,000. It cannot be doubted that this unnatural separation of the most vital part of the currency from its proper function has frequently, for a shorter or longer time, had the effect to give an adverse exchange in the mass of our dealings with foreign markets; when, if such separation had not been enforced, the exchange would have been favorable to the U. S. There are no means of determining the exact injury inflicted on our commerce by this pernicious policy. Twice during its term the country has been forced into the suspension of specie payments; and for the greater part of the period from the adoption of that policy to the present time our labor, industry, trade, and commerce have been subject to disorder, embarrassment, and disaster. In the year 1853, when Mr. Guthrie took charge of the treasury department, he advised Congress that the accumulation of gold in the vaults of the government was such as to create alarm in commercial and financial circles, and that it was an immediate necessity to adopt measures for the restoration of the treasury accumulations to the channels of commerce. In pursuance of an act of Congress authorizing the secretary of the treasury in his discretion to purchase the public debt at the current market-price, he paid out of the national treasury on that account, between Mar., 1853, and Nov., 1856, $48,060,787. "If there had been no public debt," he said in his report to Congress on the subject, "and no means of disbursing this large sum and again giving it to the channels of commerce, the accumulated revenue would have acted fatally on the banks and on trade." How could this accumulation of gold in the treasury have acted fatally otherwise than through the foreign exchange? Since the suspension of specie payments in Dec., 1861, the treasury balances have been subject to depletion by the payment of interest on the public debt and by sales of gold in the market, all other disbursements of the government being made in the paper currency. The amount of gold on hand has varied from $80,000,000 to above $100,000,000, and of gold and currency together from $130,000,000 to $175,000,000. The cost of gold in currency has been entirely independent of the state of our commercial debt with foreign countries. Being no longer in circulation as money, it has taken the place of a commodity in the market, and like any other commodity has been subject to all the accidents of extreme fluctuation. The following quotations exhibit the currency price of gold for ten years following 1862:

	Lowest.	Highest.		Lowest.	Highest.
1862	100	134	1868	132	150
1863	122	161	1869	119	145
1864	151	285	1870	110	123
1865	128	235	1871	110	115
1866	125	168	1872	109	116
1867	132	146			

During this period of financial anarchy the foreign exchange was quoted in gold, without reference to its domestic fluctuations in currency. J. S. GIBBONS.

Exchange, Bill of. See BILL OF EXCHANGE, by PROF. T. W. DWIGHT, LL.D.

Exchange Hotel, a township of Montgomery co., Ala. Pop. 1600.

Exchequer [It. *scacco*, a "chessboard"; Ger. *Schatz*, a "treasure"], a British court of record which takes cognizance of all matters relating to the customs, excise, and revenue affairs generally; also, one of the courts of common law in England. "The court of exchequer was originally the court wherein all matters relating to the royal

revenues were adjudicated upon." The British exchequer is to the Crown what the treasury of the U. S. is to the government. The chancellor of the exchequer is the first finance minister of the Crown. In 1697, while the old metallic money of the realm was in process of recoinage, the embarrassment both of the government and of the Bank of England became extreme. The credit of both sunk to a very low point. The government issued exchequer *tallies* and *orders* on the exchequer, but these very soon fell to 60 per cent. discount. The bank-bills were at 20 per cent. discount. The bank resorted to a very bold expedient for the restoration of its affairs; it advertised for £1,000,000 of new capital, and agreed to take four-fifths of it in the discredited exchequer tallies and orders. The whole amount was eagerly subscribed. The "tottering exchequer" was relieved of £800,000 of "promises to pay," and the subscribers to the whole million were involved in the necessity of carrying the bank through its crisis of embarrassment. The chancellor of the exchequer appreciated the great service rendered by the institution, and obtained a renewal of its charter for five years, with an exemption from all rate, tax, assessment, or imposition of its capital stock, with all profits accrued. These measures improved the credit of the bank, and the chancellor was inspired to invent a new instrument which became known as an *exchequer bill*. The exchequer bill is an exact counterpart of the treasury note of the government of the U. S., being nothing more or less than a promissory note payable at a certain date with interest. It is issued by authority of Parliament in emergencies of great pressure. Exchequer bills are a security held as a reserve by the bankers and by the Bank of England, which freely makes advances upon or purchases them outright. They are a recognized security, differing in no essential respect from the U. S. treasury notes, of which they are probably the original. But the British government, like that of the U. S., has occasionally allowed itself to issue more than the country could readily float. Between Mar. 13 and April 24, 1847, there was an extraordinary export of gold in payment for breadstuffs, and about the same time the government had occasion to borrow of the bank £3,500,000 to pay its dividends. A severe pressure ensued, and the bank refused to grant loans on exchequer bills. (For the best account extant of the operations and conduct of the British exchequer, see Gladstone's budget speeches for 1853, 1860–63, and on tax-bills 1861, and charities 1863, 1 vol., London.) J. S. Gibbons.

Exchequer Chamber, Court of, in England, was originally a court of all the judges in England, assembled for the decision of matters of law. By 1 Will. IV. c. 70, this court is constituted the proper tribunal for the trial of writs of error from the three superior courts of common law. The judges of two of these courts always form the court of appeal, which reviews the decisions of the third. (See Courts, by George Chase, LL.B.)

Exchequer, Chancellor of the, is the title of the highest finance minister of the British government. This office is from its nature necessarily entrusted to a commoner. When the prime minister is a member of the House of Commons, he sometimes holds the office of chancellor of the exchequer.

Exchequer, Court of, in England, is one of the supreme courts of common law. It was originally established for the recovery of the king's debts and ordinary revenues of the Crown. The judges of this court consisted originally of the lord treasurer, the chancellor of the exchequer, and three puisne judges, which last were called barons of the exchequer. In its modern shape it is, in fact, a combination of eight distinct ancient courts. It acquired concurrent jurisdiction with the other two superior courts in all personal actions by the fiction of the plaintiff being a debtor to the king—a fiction which is now removed. It has exclusive jurisdiction in cases in which the royal revenue is concerned. It had formerly also an equitable jurisdiction, which was abolished by 5 Vict. c. 5, and transferred to the court of chancery. The court now consists of five judges—viz., the chief baron and four barons of exchequer. From this court an appeal lies in error to the court of Exchequer Chamber (which see; also Courts).

Ireland has a court of exchequer, consisting of a lord chief-baron, three barons, and a master, with the necessary clerks and other inferior officers. Scotland had anciently an exchequer court which decided questions relating to revenues and customs, and to honors, estates, forfeitures, and penalties arising to the Crown. This court has been lately abolished, but there is still a lord ordinary in exchequer for Scotland.

Exchequer Tallies. The English exchequer formerly checked its accounts by means of wooden tallies, as follows: Seasoned wands of hazel, ash, or willow were inscribed on one side with the sum for which the tally was an acknowledgment, and on the other with the Roman characters indicative of the same sum, with the date and payer's name. Notches of varied appearance stood for various amounts. The deputy chancellor then split the stick with knife and mallet in such a way that each check was divided; and when the payer presented his tally for payment, it was first matched with its corresponding tally in the exchequer office. This ancient and clumsy device was nevertheless an almost perfect protection against forged applications for money. The use of the tally was a very ancient device, and was not abolished in England until 1783. The old tallies were stored in the Parliament House, and their presence in 1834 is believed to have caused the destruction of that building by fire.

Excip'ient [Lat. *excip'iens*, pres. part. of the verb *excip'io*, to "receive"], or **Ve'hicle,** in pharmacy, is an inert substance used to give form and consistence to solid preparations, such as pills and dragées, or to give palatability and the necessary qualities for administration to any medicine. The various conserves, also honey, treacle, simple syrups, glycerine, white of egg, and mucilage of acacia, are among the most useful excipients.

Excise [Lat. *excido, excisus*, to "cut off"], originally an English tax imposed chiefly upon goods of home produce destined for home consumption. It was the first ameliorated form of collecting inland revenues after the exactions of the feudal period. The impossibility of taxing people equitably according to their revenue by any system of capitation suggested the plan of levying an impost on particular commodities. But that impost might not fall equitably between the seller and the consumer. The starting idea of the excise was therefore to tax *expenses*. A consumer would buy the necessaries of life, but he would not be likely to buy more than he wanted; and consequently his expenses were fixed upon as the most accurate measure of his consumption. The tax on specific articles was intended to be an indirect tax on his expenses. The raising of revenue by this method was further commended because it afforded less facility for cheating the government than the smuggling of foreign goods. In the U. S. the term excise is applied almost exclusively to the tax on fermented or spirituous liquors, and the receipts are classed under the head of internal revenue. The following list embraces the sources from which this branch of the revenue was derived in the years 1872 and 1873, with the total of each year (for details see the report of the commissioner): spirits, distilled from apples, peaches, grapes, etc.; rectifiers of liquors, dealers, manufacturers of stills, stamps for distilled spirits intended for export, stamps for warehouses and rectifiers; and various sources not named; total of revenue for 1872, $49,475,516; for 1873, $52,099,371. In the U. S. the distinction between the excise taxes and the duties on imports, which include all the revenue of the government derived from imposts, is that of *direct* and *indirect*. (See Internal Revenue and Taxation.) The history of the operation of the old excise laws in England throws much light on this subject. It was not so much the amount of the impost, but its interference with the free course of manufactures, inventions, and the introduction of machinery that led to serious industrial evils. The laws of excise, says Sir Morton Peto, "compelled every manufacturer to manage his trade, not according to the teachings of his own experience, but by act of Parliament, which imposed upon him restrictive regulations, and taught him nothing except how to pay a tax." The result was, according to the same authority, "inferiority in the quality of the articles produced, which inferiority lost us [England] no inconsiderable proportion of the market of the world." The repeal of the old excise duties was begun in 1844 by Sir Robert Peel, and was first applied to glass. The consumption of this article was less in England in 1830 than it was in 1794. The removal of the tax gave new life to the manufacture. From the many uses of economy, comfort, and health to which it is subservient may be inferred the deprivations suffered for the want of it. The houses of the mass of the people, comparatively with the present day, were scarcely habitable. Even hospitals were without sufficiency of light and protection from the moist, cold atmosphere of the country. The residences of the common people were abodes of discomfort and sickness. The success of the manufacture carried with it the most beneficent ameliorations. England had been obliged to import all her glass for optical instruments. "If the excise duties had not been repealed in 1845," says Sir Morton Peto, "the Crystal Palace of 1851 could scarcely have been constructed." The excise on bricks prevented the growth of towns, and added permanently to the rent of houses. The tax on soap was not removed till 1853. A sensible improvement followed in sanitary conditions, as it was impossible without soap to maintain the cleanliness necessary to health. The repeal of the excise on paper resulted in immensely increased con-

sumption of the article in wrappers for goods, paper collars and cuffs, the cost of which is less than that of washing linen, and paper napkins, half a dozen of these costing less than the washing of a single one of linen. Before the repeal of this tax in England merchants had their letter envelopes made of such thin paper that the postage stamp frequently outweighed the envelope itself, and there was great insecurity in commercial remittances. Up to 1833 the taxes on pipes and tiles prevented the drainage of land, repressed the agricultural capabilities of the soil, and both increased the cost of living and reduced the quality of food. It is from such experience as this that statesmen are enlightened as to the methods of administering the power of levying imposts on the labor and industry of a nation. While no sophistry can convert taxation into anything but what it is —a burden, and often a curse—its oppressions may be lightened, and the stimulus of necessity may often be made auxiliary to the development of recuperative powers, by which the burden and the curse may be overcome by blessings. (See PETO's work on taxation, and the budget speeches of MR. GLADSTONE (1st vol., London.) For information concerning excise taxes in the U. S., see the reports of the commissioner of internal revenue.)

J. S. GIBBONS.

Ex'cito-mo'tor Action, in physiology, is that variety of reflex action which, arising from impressions made at the periphery (internal or external), is first transmitted by afferent nerve-filaments to a nerve-centre, and thence reflected without volition along motor (deferent) nerve-filaments to a muscle, which is thereby aroused to action. For example, a sudden impression of light causes the pupil of the eye to contract; the presence of a particle of food in the glottis causes intense involuntary coughing. (See REFLEX ACTION.) Excito-motor action is peculiarly active in very young children and in many of the lower animals. In some diseases (tetanus, hydrophobia, strychnia poisoning) it is immensely increased. Chloral, belladonna, curari poison, and especially the alkaloid curaria, all appear powerfully to reduce action of this kind.

Exclu'sion Bill, in English history, a bill which was designed to exclude the duke of York (King James II.) from the throne, because he was a Roman Catholic. It was adopted by the House of Commons in 1679, but was rejected by the House of Lords.

Excommunica'tion [Lat. *excommunicatio*, from *ex*, "out" or "out from," and *communico, communica'tum*, to "share," to "partake;" the act of putting one out from, so that he has no share in, the privileges and protection of the Church], the formal expulsion of a person from privileges religious or social, inflicted by church authority upon persons accused of misconduct or heresy. The ancient Israelites excommunicated offenders by exclusion from the camp, by "cutting off from the people," and in later times by "putting out of the synagogue." This punishment, in extreme cases at least, was a social interdict of the severest kind. Excommunication in the Christian Church was established by Christ's teachings, and by the precept and example of the apostles, and was necessary both for the self-preservation of the Church and for the spiritual and moral good of the offender. In early times—as also in the Roman Catholic and in several Protestant churches at present—there was a lesser and a greater excommunication; the former a virtual suspension from church privileges, the latter a formal expulsion. The greater excommunication in the Latin Church is less severe than the anathema. Excommunication was not unfrequently employed by the popes in former times as a punishment for refractory monarchs, and even for whole nations, but in later times it has not been so employed, the so-called excommunication of Victor Emmanuel in 1860 being merely a statement of the ecclesiastical penalties which the pope might inflict upon the invaders of the pontifical domains. In Prussia and Switzerland the excommunication of the Old Catholic priests by the Catholic bishops has recently brought on severe conflicts between the State and the Church.

Exe (anc. *Isaca*), a river of England, rises in Exmoor, in Somersetshire, flows generally southward through Devonshire, and after a course of 54 miles enters the English Channel at Exmouth. The chief towns on its banks are Tiverton and Exeter.

Execu'tion [Lat. *execu'tio*, from *ex*, "out," and *se'quor, secu'tus*, to "follow;" literally, a "following or carrying out" of some design or of a legal sentence], the infliction of the death-penalty by the proper civil, military, or naval authorities. In the U. S. this act is performed by the county sheriff in the precincts of a jail or prison, in presence of certain officials and other witnesses, and hanging is the only method employed. Military executions are performed by a provost-marshal and his guard, either by shooting with small-arms or by hanging. Naval executions are generally by hanging at the yard-arm. In Western Europe hanging is the more common method in civil cases, except in France, where the guillotine is employed, and in Spain the garrote takes its place. Burning, drowning, stoning, and a great variety of methods have been practised in former times. In the Indian mutiny of 1857 many of the captured Sepoys were blown from the cannon's mouth.

Execution, the formality of signing, sealing, and delivering a deed, or of signing and publishing a will; in criminal law, the carrying into effect the sentence of the law by putting the criminal to death; in civil actions, the carrying out the final judgment of the court, or, more strictly, the writ directing the sheriff, coroner, or marshal to carry such judgment into effect.

Under the law of England, there were three writs in constant use to enforce a judgment for the payment of money: 1st, a writ of *fieri facias*, commonly called a *fi. fa.*, directing the officer to cause to be made the amount of the judgment out of the goods and chattels of the debtor; 2d, a writ of *elegit*, given by statute of 13 Edw. II., directing the officer to deliver the goods and chattels of the debtor to the creditor at an appraised value, in satisfaction of the judgment, and, if these are insufficient, to put him in possession of one-half the debtor's land till the rents and profits satisfy the judgment; 3d, a writ of *capias ad satisfaciendum*, commonly called a *ca. sa.*, directing the officer to arrest the debtor and keep him in confinement till he satisfies the judgment.

The English practice has been somewhat changed in the State of New York. There are two writs of execution—one against the property, and one against the person, of the debtor. The former, which resembles the *fi. fa.*, directs the sheriff to satisfy the judgment out of the personal property of the debtor within the county, and, if sufficient cannot be found, then out of his real property, and to return the writ within sixty days. The latter, like the *ca. sa.*, directs the officer to arrest the debtor and keep him in jail till he pays the judgment or is discharged according to law. Since the act of 1831 abolishing imprisonment for debt, this writ is allowed in comparatively few cases, as when the debt was contracted in fraud, or the debtor has attempted to remove his property, or has violated his duty in some trust relation. Under the execution against the property the sheriff sells at public auction the real and personal property of the debtor, though a variety of articles necessary for the prosecution of a business and support of a family are exempted, as also a homestead to the value of one thousand dollars, subject to certain conditions. If the judgment is for the recovery of specific real or personal property, the execution directs the sheriff to deliver such property to the plaintiff. Many of the other States have closely followed the New York practice.

Although these proceedings are instituted by the party in whose favor the judgment is rendered, they are considered as the acts of the law, and the officer entrusted with their performance is responsible to the party aggrieved for any misconduct or neglect of duty.

Executive Department, The, in the U. S. government, is that branch of the public service which attends to the execution of the laws of the general government. This department is under the direct control of the President, who is the principal executive officer. The duties of the executive department are the most extensive of all. It makes all civil, naval, and military appointments, and manages the army and navy, collects customs and internal revenue, sells public lands, and pays all appropriations authorized by Congress. Each of the secretaries of inferior departments, including the postmaster-general and attorney-general, take rank next the President as officers of the executive department. They together constitute the so-called "Cabinet," which, by usage, has become a consulting or advisory council to the President. These officers are the secretary of state, of the treasury, of the interior, of war, of the navy, and the postmaster-general and the attorney-general. (See UNITED STATES.)

Exec'utor [from the Lat. *ex*, "out," and *sequor, secutus*, to "follow"], one to whom a testator commits the execution of his last will. The will is the source of the executor's title, and the probate (or proof) of the will is merely evidence of it. As a general rule, any one capable of making a contract can be an executor. By the law of England, an infant can not as executor after the age of seventeen. In many of the U. S. it is provided by statute that no person under twenty-one is competent to act as executor. The chief duties of an executor are to bury the deceased in a manner suitable to the estate which he leaves, to prove the will, make an inventory of his goods, collect the assets, and pay the debts and legacies. An executor has general control over the personal estate, and possesses the same property in it as the testator had when living, and the same remedies to recover it. He has no power over the real

estate, unless it is given to him by the will, or unless the local law gives it to him when the personal property is insufficient to pay the debts. When he has authority given to him in a will to control the real estate, he is not deemed to act as an executor, but either as a trustee or the grantee of a power, according to the nature of the authority conferred upon him.

An executor *de son tort* is one who interferes with the goods of a deceased without lawful authority. He has the trouble of an executor without the advantages. He may be sued as executor if any assets have come into his hands, but cannot bring an action as executor.

In some States, executors are required to give bonds for the faithful discharge of their duties, and in others the probate court has a right to require them to furnish security if there is any doubt of their solvency.

Exege'sis, or Exeget'ical Theol'ogy [Gr. ἐξήγησις, from ἐξηγέομαι, to "lead," also to "teach," to "expound" (from ἐξ for ἐκ, "out," also "intensive," and ἡγέομαι, to "lead," to "guide," to "point out the way"); ἐξηγητής, originally, among the Athenians, the interpreter of the oracles of Delphi, the signs of heaven, and sacred rites; among Christians, the interpreter of the Holy Scriptures], is the first and most important part of theological science, and covers the whole field of biblical literature, or all that pertains to the learned explanation of the Old and New Testaments. It originated among the Jewish rabbis, but was afterwards far more extensively cultivated among the Christian Fathers, the Reformers, and the divines of all ages. It is taught as a science and practised as an art in all theological institutions, and its results are applied from every pulpit throughout the Christian world. No knowledge is more useful and indispensable to a clergyman than the knowledge of the Bible, which he has to explain from Sunday to Sunday, and which among Protestants is the only infallible source and rule of faith and morals and all that pertains to the eternal interests of men.

I. *Kinds of Exegesis.*—(1) *Philological* or grammatico-historical exegesis is the basis on which all other interpretation and application must rest. It aims simply at the meaning of the writer according to the recognized laws of language and the *usus loquendi* at the time of composition, and according to the historical situation of the writer, irrespective of any doctrinal or sectarian bias. It implies a thorough knowledge of Greek and Hebrew, and familiarity with contemporary literature. (2) *Theological* exegesis develops the doctrinal and ethical ideas of the writer in organic connection with the whole teaching of the Scriptures and according to the analogy of faith. (3) *Homiletical* or practical exegesis is the application of the well-ascertained results of grammatical and theological interpretation to the wants of the Christian congregation, and belongs properly to the pulpit.

II. *Auxiliary and Supplementary Branches.*—(1) *Sacred Philology*, the science of the languages in which the Bible was originally written—viz., the Hebrew in the Old Testament (with a few sections in the cognate Semitic dialect called Chaldee or East Aramaic), and the Greek in the New Testament. The latter is not the classical Greek, but the Macedonian or Alexandrian dialect, with a strong Hebrew coloring (hence called the Hellenistic, because spoken by the Hellenists, *i. e.* the Greek Jews) and the infusion of the spirit of Christianity, which created new words or inspired a deeper meaning into old words. The New Testament Greek requires, therefore, a particular study, special grammars (*i. e.* Winer, Buttmann, Jr.), and special dictionaries (Wahl, Bretschneider, Wilke, Grimm, Cremer, Robinson).

(2) *Biblical Archæology* or *Antiquities*—*i. e.* a systematic description of the external and internal condition of the nations among which, and the countries in which, the Bible was composed. This includes, again, the geography and natural history of Palestine and adjacent countries, the topography of Jerusalem, an account of the domestic habits, social institutions, agriculture, arts and science, religious rites, and ceremonies of the Hebrews. The material of Jewish antiquities is derived mostly from the Bible itself, but also from Philo and Josephus, the "Talmud," the monumental remains of Egypt, Assyria, Babylon, and the accounts of modern explorers down to the labors of the English and American Palestine Exploration Societies now in progress. Dr. Robinson of New York (died 1863) broke the way for truly independent critical research of the localities of Jerusalem above the surface, while the Palestine Exploration Society of England has begun to make us acquainted with subterranean Jerusalem as it was before the destruction.

(3) *Biblical Criticism* aims at the approximate restoration of the original text of the Bible as it came from the hands of the inspired authors. The autographs being lost, we are confined to the oldest uncial manuscripts, which date from the fourth and fifth centuries. Besides, we have partial and secondary sources of the Greek text in the very numerous Scripture quotations of the Christian Fathers (Origen, Irenæus, Chrysostom, etc.), and the old translations (especially the Syriac, Peshito, and the Latin Itala and the improved Vulgate of Jerome). Textual criticism includes a discussion of the merits of the received text (*textus receptus*, derived from Erasmus, Stephens, Beza, and Elzevir), the principles for ascertaining the oldest and purest text, the classification of manuscripts and different readings, and a history of the printed text from Erasmus and the Complutensian Polyglot down to Lachmann, Tischendorf, and Tregelles. There is a gradual approach to an agreement among the best critics, and the conviction of the essential integrity of the primitive text has been greatly strengthened by the latest discoveries (*e. g.* the "Codex Sinaiticus") and investigations.

(4) *Historico-Critical Introduction to the Books of the Old and New Testaments* is a literary history of the Bible, and includes all the introductory information necessary for the proper understanding of its contents, as the question of the genuineness and integrity of the book, the persons addressed, the place and time of composition, the object and aim of the writer. It gives also a history of the canon or collection of the several books of the Bible into one authoritative code, distinct from all other books, and recognized as a rule (κανών) of faith and morals by those who receive them. The principal works on introduction are by De Wette, Hug, Reuss, Bleek, Guericke, Horne, Davidson. Compare also the "Bible Dictionaries" of Kitto (3d ed. by William L. Alexander, 3 vols.), William Smith (ed. with improvements by Hackett and Abbot, in 4 vols.), Fairbairn, Winer, Schenkel.

(5) *Biblical Hermeneutics*—*i. e.* the science of the principles of interpretation, and the necessary qualifications for an expounder of the Scriptures. These qualifications are partly intellectual (familiarity with the general laws of thought and speech, knowledge of the particular languages of the Bible, sound judgment) and partly moral (freedom from prejudice, readiness to do justice to the author, sympathy with his spirit and ideas).

(6) *Biblical Theology of the Old and New Testaments* is a summing up of the results of exegesis in systematic order, and presents a full view of the teaching of the Scriptures, irrespective of the subsequent systems of denominational dogmatics and ethics derived from them. This branch of exegetical theology is of recent growth, and has thus far been mostly cultivated by Continental scholars. There are also special treatises on the theology of Christ, the theology of Paul, John, and Peter. Each of the apostles, as he has his own peculiar style, represents also a special aspect of the Christian system; yet all harmonize and exhibit together the fulness of the gospel. (Compare the works of Schmid and Van Oosterzee on New Testament Theology, recently translated into English; Ewald, Schultz, and Oehler on Old Testament Theology.)

III. *History of Exegesis and Principal Commentaries.*—(1) *Jewish* exegesis, confined to the Old Testament. It began soon after the close of the canon. It was especially devoted to the Law (the Thorah), *i. e.* the Pentateuch, and derived from it minute rules for the individual, social, and ecclesiastical relations. The body of these interpretations is called *Midrash*. The prevailing method of exegesis was the rabbinical or literal; it excluded all foreign ideas, and was subservient to the strict legalism of the Pharisees. But among the Hellenist (Greek-speaking) Jews, especially in Alexandria, the allegorizing method obtained favor, especially through Philo (died about 40 A. D.), who endeavored to combine the Mosaic religion with Platonic philosophy, and prepared the way for the allegorizing exegesis of Clement and Origen of Alexandria. The Jewish rabbins of the Middle Ages cultivated grammatical exegesis at a time when the knowledge of Hebrew had died out in the Christian Church. The most distinguished among them are Ibn Ezra (died 1167), R. Sal. Isaak or Raschi (died 1105), David Kimchi (died 1190), Moses Maimonides (died 1204). Their commentaries are printed separately, and also in the so-called Rabbinical Bibles (*e. g.* of Buxtorf, Bâle, 1618, 3 vols. fol.).

(2) *Patristic Exegesis.* The first use made of the Bible in the Church was practical and homiletical. It was to the early Christians what it still is to the great mass of believers, and will be to the end of time—a book of life, of spiritual instruction and edification, of hope and comfort. Scientific or learned exegesis began when the Bible was perverted by heretics and made to serve all sorts of errors. The Greek Church took the lead. Origen (180–254), the greatest scholar of his age, a man of genius and iron industry, is the father of critical exegesis. He is full of suggestive ideas, but far from being sound. His theory of hermeneutics is untenable, and opens the way for the most fanciful and arbitrary expositions or impositions. He distinguishes three senses in the Bible, corresponding to the

three parts of man: (*a*) a literal or bodily sense; (*b*) a moral or psychic sense; (*c*) an allegorical or mystic, spiritual sense. Where the literal sense is offensive, he escaped the difficulty by adopting a purely spiritual sense. The greatest commentators of the Greek Church are Chrysostom (died 407), who in his "Homilies" explained the principal books of the Old and New Testaments, Theodore of Mopsuestia (died 429), Theodoret of Cyros (died 457). Among the Latin Fathers, Augustine (died 430) is the profoundest and most spiritual, Jerome (died 419) the most learned expounder. The latter achieved the highest merit by his improved Latin version of the Bible (the Vulgate), which remains to this day the standard version of the Roman Church. The Council of Trent forbade the interpretation of Scriptures except according to "the unanimous consent of the Fathers." But this rule would prevent all progress in theology; and besides, such a "unanimous consent" does not exist except in the most fundamental doctrines.

(3) *Mediæval exegesis* was purely traditional, and consisted of brief glosses (*glossaria*) or of extracts from the Fathers (called *catenæ Patrum*). The original languages of the Bible were unknown in the West, and even the first among the scholastics had to depend upon Jerome's version for their knowledge of God's word. The prevailing method distinguished four senses of the Scriptures: (*a*) the literal or historical; (*b*) the spiritual or mystic, corresponding to faith, teaching what to believe (*credenda*); (*c*) the moral or tropological, which corresponds to love or charity, and teaches what to do (*agenda*); (*d*) the anagogical, which refers to hope (*speranda*). The principal patristic compilations are (*a*) in the Greek Church, those of Œcumenius (died 990), Theophylactus (died 1007), Enthymais Zigabenus (died 1118), and Nicephorus (fourteenth century); (*b*) in the Latin Church, Wallafried Strabo (died 849), Thomas Aquinas (died 1274). The *Catena aurea in Evangelia* of Aquinas has been recently reproduced in an English translation by Pusey, Keble, and Newman. Among the more independent biblical scholars of the Middle Ages who prepared the way for the Reformation must be mentioned Nicolaus à Lyra (died 1340: "Si Lyra non lyrasset, Lutherus non saltasset"), and Laurentius Valla (died 1465).

(4) The exegesis of the *Protestant Reformers* of the sixteenth century marks a new epoch. It is full of enthusiasm for the word of God in the Bible as the only rule of Christian faith and practice, and free from the slavery of ecclesiastical tradition. It went directly to the original Greek and Hebrew Scriptures, and furnished the best translations for the benefit of the people, while Romanism regards the Bible as a book for the priesthood, and discourages or prohibits efforts for its general circulation without note or comments. All the Reformers wrote commentaries more or less extensive on various books of the Bible—Luther (died 1546), Melanchthon (died 1560), Zwingli (died 1531), Œcolampadius (died 1531)—but the ablest of them are Calvin (died 1564) and his pupil Beza (died 1603). Calvin combines almost all the qualifications of an expounder in rare harmony, and his commentaries on Genesis, the Psalms, the Prophets, and all the books of the New Testament (except Revelation) are valuable to this day.

(5) Protestant commentaries of the seventeenth and eighteenth centuries by Hugo Grotius (died 1645, Arminian), Vitringa (died 1722, Dutch Calvinist), Hammond (died 1660, Church of England), Mathew Poole (Presbyterian, died 1679, "Annotations upon the Whole Bible," an English synopsis from his Latin synopsis), Matthew Henry (Independent, died 1714, the best homiletical commentator of England), John Gill (Baptist, died 1771), Philip Doddridge (Independent, died 1751, author of "Family Expositor"), Calovius (Lutheran, died 1686, "Biblia Illustrata" versus Grotius), J. A. Bengel (Lutheran, died 1752, author of the "Gnomon of the New Testament," in Latin, twice translated into English, an admirable specimen of *multum in parvo*). Collective works: "Critici Sacri," London, 1660, 9 tom.; Amsterdam, 1698–1732, in 13 vols. (compiled from the principal commentators as an appendix to Walton's "Polyglot," under the direction of Bishop Pearson and others); Poole's "Synopsis Criticorum aliorumque S. Scripturæ interpretum," London, 1669–76, 4 vols. in 5 fol. (a very useful abridgment from the "Critici Sacri" and other commentators).

(6) Modern commentaries, chiefly German, English, and American: (*a*) On the whole Bible: Lange's "Bibelwerk," Bielefeld and Leipsic, 1857 seq. (a threefold commentary, critical, doctrinal, and homiletical, prepared by a number of Continental, mostly German, divines, and to be completed in about 30 parts, chiefly for the use of ministers and students); the same in English, with large improvements and additions by more than forty American scholars of all denominations, under the editorial care of Philip Schaff, New York and Edinburgh, 1864 seq. (to be completed in 23 vols., of which 18 had appeared in 1873); "The Speaker's Commentary," suggested by the Speaker of the House of Commons, ed. by Canon F. C. Cook, aided by a number of bishops and presbyters of the Church of England, London and New York, 1871 seq., to be completed in 8 vols. (so far two vols., from Genesis to Kings, mainly for the lay reader). (*b*) On the New Testament: Olshausen, De Wette, and especially Meyer (the first philological commentator now living), among the Germans, Alford and Wordsworth among the English; all for critical students. Of popular commentaries of the New Testament, Barnes has had by far the widest circulation in America and England. The present century has also produced a large number of exegetical works of the first order on separate books of the Bible, which it would be impossible here to enumerate. Among recent commentators on one or more books of the Old Testament, Gesenius, Ewald, Hupfeld, Hitzig, Hengstenberg, Delitzsch, Schlottmann, Stuart, Joseph A. Alexander, occupy the first rank. Of New Testament commentators must be mentioned Winer, Fritzsche, Tholuck, Lücke, Bleek, Harless, Godet, Stuart, Hodge, Stanley, Jowett, Ellicott, and Lightfoot. Among these, again, Tholuck on Romans and the Sermon on the Mount, Lücke on the Writings of St. John, Harless on Ephesians, Hodge on Romans, Ellicott on Galatians, Ephesians, Thessalonians, and Pastoral Epistles (republished in Andover), Lightfoot on Galatians and Philippians, are most useful for the critical study of the Greek Testament.

Philip Schaff.

Ex'eter [Lat. *Isca* or *Exonia*], a city and seaport of England, the capital of Devonshire and a separate county, is on the river Exe, about 10 miles from the sea, and 170 miles W. S. W. of London, with which it is connected by railway. It is pleasantly situated on the sides and summit of an acclivity, and is well built, well paved, and liberally supplied with water. Exeter is the see of a bishop, and has a magnificent cathedral, which was commenced in 1280; it is 408 feet long, and has two Norman towers 145 feet high. The W. front is richly decorated, and presents a façade which is one of the most beautiful in England. In one of the towers is the Great Tom of Exeter, or Peter's Bell, which weighs 12,500 pounds. Exeter contains a theatre, twenty-four Episcopal churches and chapels, and a lunatic asylum. It returns two members to Parliament. Vessels of 400 tons can ascend the Exe to this place, from which dairy produce, fruits, and other articles are exported. Here are several large nurseries. Pop. of municipal borough in 1871, 34,646.

Exeter, a post-village of Huron co., Ontario, Canada, has quite extensive manufactures and a thriving trade. Pop. about 1000.

Exeter, a post-township of Penobscot co., Me. It has manufactures of lumber, shingles, carriages, etc. P. 1424.

Exeter, a post-township of Monroe co., Mich. P. 1067.

Exeter, a post-village, one of the capitals of Rockingham co., N. H., on the Squamscott River and the Boston and Maine R. R., 50 miles N. of Boston. It has the county offices, a national bank, two savings banks, four hotels, Phillips Academy, a richly-endowed institution founded in 1781, Robinson's Female Seminary, a high school, one weekly newspaper, seven churches, a large cotton-mill and machine-shop, railroad round-house, and manufactures of lumber, castings, and carriages. Pop. of Exeter township, 3437. Charles Marseilles, Pub. "News Letter."

Exeter, a post-twp. of Otsego co., N. Y. Pop. 1256.

Exeter, a township of Berks co., Pa. Pop. 2239.

Exeter, a post-township of Luzerne co., Pa. Pop. 742.

Exeter, a township of Wyoming co., Pa. Pop. 211.

Exeter, a post-twp. of Washington co., R. I. P. 1462.

Exeter, a post-township of Green co., Wis. Pop. 949.

Exeter Hall, a building in the Strand, London, erected in 1831, and remodelled in 1850. It is celebrated as the place of assembly of many of the religious and philanthropic societies of England. "Exeter Hall philanthropy" is a term applied to public efforts in behalf of the poor and degraded, implying (often with injustice) that such efforts are ostentatious and ineffectual.

Ex'ile. This word is used of the person who, either voluntarily or by penal sentence, leaves his own country in order to escape the consequences to life, liberty, or property that residence at home would bring with it. It also denotes the state of such an exile, as we say to go *into exile*. It thus answers to two Latin words, *exsul* or *exul*, and *exilium*, which stand related like *consul* and *consilium*, and are derived from *ex*, and the root of *solum*, "soil," "ground," as the Latins said of an exile, *qui solum vertit*, "he who changes his soil" or "dwelling-place." It differs from *banishment* (derived from *ban*, "edict," "proclamation"), in

that the latter strictly implies a penalty or act of the supreme authority, driving a person away from his home and country, while *exile* has no such necessary sense. It differs from *captivity* in a foreign land, in that a captive is not a free person, but under the enemy's power. The Greeks in their usages and legislation were familiar with voluntary exile on account of involuntary homicide, with ostracism, a political contrivance, especially at Athens, in order to get rid of a powerful party-leader, and with exile especially for life. In the two former cases a man retained his property, and return to his native land was allowed; in the last, besides lifelong absence, he suffered the ills of confiscation of his goods. At Rome, while the republic lasted, a person, before sentence for crime, could go to a foreign country; and there were even treaties with certain states by virtue of which a Roman, and *vice versâ* a citizen of such a state, had a liberty of living in exile in each other's country conceded to them. Verres and Milo, with many others, thus left the Roman dominions to escape a sentence. Exile was also a penalty for certain crimes, or, as in the case of Cicero, was decreed by vote of the comitia. It was called *aquæ et ignis interdictio—i. e.* prohibition from the use of fire and water within certain limits. Under the empire the forms of exile in use went by the names of *relegatio* and *deportatio*. Relegation either excluded the person affected by it from a particular place or territory, or it required him to reside at a particular place or within a particular country, without depriving him of property, citizenship, or a father's power, and did not necessarily prevent his return. Deportation, called also deportation to an island, was introduced under the emperors, and involved loss of citizenship and of property. The poet Ovid was relegated, under Augustus and by an edict, to Tomi in Lower Mœsia, where he died after ten years of exile.

Exile is as a punishment unknown to English law, unless it be in the form of transportation by act of Parliament, or as a condition of pardon by the executive for a capital or other severe punishment.

Free countries, unless overawed by superior power, have generally given refuge to political exiles, and seldom have they delivered them up on demand from the exile's country. This was the boast of Athens, which Demosthenes calls the common place of refuge for Greece; who also pronounces it to be the common usage of all men to give shelter to an exile. The connection of the exile with his native land of course ceases. The jurisdiction over him depends on the laws of the land where he is domiciled. If, as sometimes happens, he engages in plots with accomplices in his native country, he is amenable to the law of his domicile for any criminal acts he may commit within its jurisdiction. Such a person is sometimes demanded by the authorities of his original home, in order to be proceeded against by its laws and modes of trial. But a free country will refuse to surrender its territorial rights in such cases. T. D. Woolsey.

Exi'ra, a post-village, capital of Audubon co., Ia., beautifully situated on the Nishnabatona River, 70 miles W. of Des Moines, in a fertile, well-timbered region abounding in lignite, peat, potters' clay, and chalybeate mineral springs. It has a public square, two churches, a weekly newspaper, and a fine school-house. Pop. of village, 161; of township, 426. D. M. Harris, Ed. "Defender."

Ex'moor For'est, England, is partly in Devonshire and partly in Somersetshire. It is mostly uncultivated, and is occupied by dark ranges of hills and lonely valleys. The surface-rocks are Devonian slate and new red sandstone. The highest point of the hills is 1668 feet. Exmoor is partly covered with heath, and contains considerable meadow-land. It gave name to a breed of sheep, now nearly extinct. Area, 19,270 acres. Ponies are bred extensively, and iron is mined.

Ex'mouth, a town and watering-place of England, in Devonshire, is on the English Channel at the mouth of the Exe, 10 miles S. E. of Exeter. The mildness of the climate and the beauty of its scenery render it a favorite place of resort. The fisheries and lace-making are the principal industries. Here Sueno the Dane landed in 1003. Pop. with surroundings, 7538.

Ex'mouth (Edward **Pellew**), Viscount, an English admiral, born at Dover April 19, 1757. He served with distinction at the battle of Lake Champlain in Oct., 1776, and became a post-captain in 1782. In 1804 he obtained the rank of rear-admiral, and in 1808 that of vice-admiral of the blue. He was created Baron Exmouth in 1814, and was raised to the rank of admiral. He commanded a fleet which in 1816 was sent to enforce a treaty which the dey of Algiers had violated. This fleet, aided by a Dutch fleet, bombarded Algiers in August of that year, and reduced the dey to submission. He received the title of Viscount in Dec., 1816. Died Jan. 23, 1833. The title is still extant, and in the Pellew family.

Ex'ner (Franz), a German philosopher, born in 1802, became in 1831 professor of philosophy in the University of Prague, and was appointed counsellor in the Austrian ministry of public education in 1848. Died in 1853. He wrote, among other works, "Die Psychologie der Hegel'schen Schule" (1842–44), and "Uber die Lehre von der Einheit des Denkens and Seins" (1845).

Exodus [Gr. Ἔξοδος, "a going forth"]. The migration, whether by compulsion or otherwise, of any considerable body of people, as of the Moors from Spain in 1492, of the Huguenots from France after the Revocation of the Edict of Nantes in 1685, or of the Irish to the U. S. since 1847, may be called an exodus, but the term is commonly applied almost exclusively to the departure of the Israelites from Egypt under the leadership of Moses. From the biblical narrative it is not quite clear how long they had been in Egypt—whether a little more than four centuries, or only a little more than two. In Exodus xii. 40, we read: "Now the sojourning of the children of Israel, who dwelt in Egypt, was *four hundred and thirty* years." But the Septuagint and the Samaritan Pentateuch agree in making the four hundred and thirty years cover also the previous residence in Canaan. And this appears to have been the chronology of Paul (see Gal. iii. 17). Josephus sometimes (*Ant.*, 2, 9, 1; *Jew. W.*, 5, 9, 4) says 400 years, but in *Ant.*, 2, 15, 2, he says that "the Israelites left Egypt 430 years after the entrance of Abraham into Canaan, and 215 years after Jacob's coming into Egypt." The great increase in population, from the nomadic family of seventy persons to the agricultural nation of two and a half millions, would seem to require the longer period, unless we assume the incorporation by circumcision of a large body of dependants into the original stock. From the genealogical tables in the first book of Chronicles, and elsewhere, it is evident that unless the time was much longer than 215 years, the generations followed one another with great rapidity; for although only four generations are named of the family to which Moses belonged, Bezaleel, the artificer, was in the seventh generation from Judah (1 Chron. ii. 3–20), the five daughters of Zelophehad in the seventh generation from Joseph, through Manasseh (Num. xxvi. 28–33), and Joshua in the eleventh generation from Joseph, through Ephraim (1 Chron. vii. 22–27). And what proof have we that in any case the links are all given? Malthus says: "It has been constantly remarked that all new colonies, settled in healthy countries, where room and food were abundant, have constantly made a rapid progress in population." Egypt, it is well known, was famous amongst the nations of antiquity not only for its animal fecundity, but also for the fertility of its human occupants. And yet the rapid increase of the Israelites in Egypt is emphasized in the history, and referred to afterwards (Ps. cv. 23, 24), as something extraordinary. It is consequently impossible for us to say whether the biblical narrative requires 430 or only 215 years.

As to the points of contact between Egyptian and Hebrew history, the time has not yet come for final conclusions. Egyptian history itself is undergoing reconstruction. But the best biblical scholars now incline to the opinion that the Israelites entered Egypt under the twelfth dynasty (Abraham under one of its earlier, and Jacob under one of its later, kings), and came out under the eighteenth, but the exact chronology has not yet been determined. They dwelt probably in the Delta, and took their departure by the Wady-t-Tumeylat, which is about halfway between the Mediterranean and the present head of the Red Sea. The point at which they crossed this sea is generally supposed to have been not far from where Suez now stands. From this point to Sinai the distance is about 150 miles. Their route to Sinai was probably through the Wady Feiran. And if the Exodus occurred in the time of Thotmes II., the fifth king of the eighteenth dynasty, the way was entirely open to them, for it has been recently ascertained that the copper-mines of the Sinaitic peninsula, which they had to pass, were not worked by the Egyptians from the reign of Thotmes I. to the seventeenth year of Thotmes III. Kadesh Barnea, the point at which they first touched the borders of Palestine, and to which, after thirty-eight years of penal wandering, they returned, has not been certainly identified, Robinson finding it on the E. side, and Palmer on the W. side, of the desert. If the Israelites were to be civilized by contact with another people, no better place could have been found, and on the whole no safer, than Egypt. The miracles by which they were delivered, and which attended them all the way through the desert until they were finally planted in their former home, made a profound impression upon the national character.

R. D. Hitchcock.

Exodus, The Book of, was so named by the Alexandrian translators of the Old Testament. The Hebrews

of Palestine designated it by its opening words, *Elleh Shemoth*, "these are the words." It consists of two distinct portions; the former (chaps. i.–xix.) describing the deliverance of the Israelites from Egypt; the latter (chaps. xx.–xl.) describing the giving of the Law. Its Mosaic authorship, though denied by some, is generally conceded. Its date depends, of course, upon that of Moses himself.

Exog'enous Plants, or **Ex'ogens** [from the Gr. ἔξω, "without," and γενω, to "be born," to "grow"], the first or most highly developed of the two primary classes of phænogamous or flowering plants. They are called exogens because their stems grow by successive external additions, and are sometimes termed *dicotyledonous*, because the seed has usually two cotyledons. This class is characterized by net-veined (reticulated) leaves, and by stems which present distinct formations of bark, wood, and pith, the wood forming a zone between the other two, and increasing, when the stem continues from year to year, by the annual addition of a new layer to the outside. The flowers are usually formed on a quinary, more rarely on a quaternary, type. The bark is very distinct from the woody or fibro-vascular part which it surrounds. A transverse section of the stem exhibits a central cellular substance (*pith*), an external cellular and fibrous ring or bark, and an intermediate woody mass traversed by *medullary rays*, which radiate from the pith to the bark. A viscid secretion called *cambium* is formed between the bark and the *alburnum* (sap-wood) in the spring, and is supposed to be the matter out of which new wood is made. The age of exogenous trees can often be computed by the concentric rings annually produced. More than 1200 rings or layers have been counted on a stump. All trees of cold or temperate climates, and most trees of tropical regions, are exogenous. The total number of exogenous plants is much greater than that of the endogens. The medullary rays are thin plates of cellular tissue, which on a cross section appear like fine lines, but in wood cut lengthwise, parallel to them, they present an appearance called *silver grain*, and their faces show as glimmering plates.

Ex'orcism [Gr. ἐξορκισμός, from ἐξ (for ἐκ), "out," and ὁρκίζω, to "adjure" (from ὅρκος, an "oath")], a ceremony designed to expel dæmons or evil spirits from persons, places, or things. Exorcisms of various kinds have been practised from remote antiquity in nearly all nations and races. The ancient Jews, as we learn from Josephus, the Talmud, and the New Testament, had a class of persons professing to be skilled in casting out devils. Miracles of this kind are recorded as having been performed by Christ and his apostles, and in the early ages of the Church a separate class of exorcists arose who claimed special powers of controlling evil spirits. Many ceremonies were instituted by them, and their powers were exerted not only over those possessed by the devil, but over all candidates for baptism, over the baptismal water, and other sacred things and places. At present in the Church of Rome there is a special order of exorcists, one of the four orders of the minor clergy. All persons in superior orders must pass through this degree. In the Greek Church a similar order exists. Exorcism is now obsolete in all Protestant denominations, though formerly recognized in several.

Exosmose. See Endosmose.

Exoteric. See Esoteric.

Exosto'sis [Gr. ἐξόστωσις (from the Gr. ἐξ, "without," and ὀστέον, a "bone")], a bony tumor, a circumscribed, non-malignant mass of bone, usually an abnormal outgrowth from one of the bones of the skeleton. In man the disease especially seats itself upon the femur or on some of the bones of the skull. In the latter case it sometimes assumes a peculiar ivory-like character (eburnized exostosis), from the presence of an excess of calcium phosphate. It is usually developed from an inflammation-exudate, and is ordinarily formed with the exact structure of true bone. The disease is commonly painless. Some classes arise from a syphilitic taint, others from a rheumatic or gouty diathesis, others from no known cause.

Some writers include all bony outgrowths, malignant and other, under this head, but the best pathologists restrict the name to the one disease. Discutient remedies, mercurials and iodides, have been recommended for this disease, but ordinarily the only cure is in ablation, which, however, is liable to be followed by erysipelas.

Expan'sion [Lat. *expansio*, from *ex*, "out," and *pando*, *pansum*, to "open," to "spread"], an increase in the bulk of solid, liquid, or gaseous matter, due to the increase of heat. Heat is believed to consist of a very rapid molecular vibration, and the addition of this motion to a collection of particles must obviously tend to separate them and enlarge the mass. Expansion accordingly takes place in nearly all solids on the addition of heat up to the point of fusion; and in most substances expansion continues through the process of fusion, and beyond it; but ice, bismuth, antimony, paraffin, and a few other substances contract in fusing, but go on expanding if heat be added after fusion.

Iodide of silver contracts uniformly under heat; and it is certain that some crystals expand in some directions and contract in others, the general result being an expansion. Non-crystalline bodies usually expand uniformly in every direction, provided heat be uniformly applied. Liquids, like solids, expand at an increasing rate with the increase of heat. Gases expand almost uniformly $\frac{1}{273}$ of their volume for 1° Fahrenheit.

Allowance is always made for expansion and contraction in large iron bridges, buildings, etc.; for if no play were allowed at the joints, hot and cold weather would distort or destroy such structures; and it must especially be remembered that superficial expansion is twice as great, and cubical expansion three times as great, as the linear.

Ex Par'te, a Latin legal phrase signifying "of one party." A commission *ex parte* in chancery is that which is taken out and executed by one side or party alone, the other party neglecting or refusing to join.

Expatriation [from the Lat. *ex*, "out," and *patria*, "one's native land"], the voluntary abandonment of one's native country with the intention of becoming a citizen of another state. The right of a person to throw off the obligation of allegiance has been denied by eminent writers and some governments. The true view would seem to be that the power to determine when the allegiance of the citizen may cease belongs to the state of which he is a member, rather than to himself. At the same time, the freedom of intercourse between nations in modern times and the interests of civilization require that the various nations should provide liberal rules by which at proper times the relation of the citizen to the state may cease, and the individual, freed from the ties of burdensome allegiance, may assume another citizenship if he so desire. In this spirit may now be found statutory declarations by leading states on this subject, as well as treaty stipulations. By the act of Congress of July 27, 1868, § 1, it is recited that the act of expatriation is a natural and inherent right of all people, and it is enacted that any declaration or instruction or decision of any officer of the government which denies, restricts, or questions the right of expatriation is inconsistent with the fundamental principle of the government. In England, by 33 Vict. ch. 14, § 6, British subjects in general cease to be such upon becoming naturalized in a foreign state. The laws of the various states upon this subject are collected under the direction of the U. S. government in a publication entitled "Opinions of the Principal Officers of the Executive Departments, and other papers, relating to Expatriation, Naturalization, and Change of Allegiance," Washington, 1873.

If the right of expatriation be admitted except in certain cases, such as where the person holds a public trust, or is liable to do military service, or is charged with crime, a question of practical difficulty remains as to the mode in which his election to abandon his citizenship shall be evidenced. In some countries—*e. g.* France and Prussia—it may be shown by the fact that the person has taken his domicile in a foreign country in such a sense that he has abandoned all intent to return to his former home. This rule is not very satisfactory, as questions of domicile are frequently very difficult of solution, as they depend upon a judicial inquiry into the intent of the party, and this in turn depends upon an examination into a great variety of circumstances, and often ranging over many years. A much more convenient test is that of the English statute already cited. This provides that naturalization in a foreign country shall be evidence of an intent to renounce English citizenship. Should the former subject wish at any time to resume his relations with England, he can be naturalized under the laws of that country. The whole subject is not so important in the domain of private law as it was formerly, when aliens were subject to serious disabilities, particularly in respect to the acquisition of land. In a political aspect it is, however, of much consequence, and it is quite desirable that Congress should pass a comprehensive statute setting forth upon what terms expatriation may take place, the evidence by which it may be properly established, and how citizenship may be resumed. The general declaration in the law of July 27, 1868, that expatriation is a natural right, etc., is of but little practical value in settling the questions that from time to time arise upon this intricate subject. There is a special point of considerable moment as to the *status* of naturalized citizens of the U. S. becoming again domiciled in their native country, as to whom other considerations are presented from those which prevail in the case of such a domicile by one

who was born an American citizen. (For further information, consult INTERNATIONAL LAW, and text-books upon that subject; also CITIZEN.) T. W. DWIGHT.

Expec'torant [from the Lat. *ex*, "out," and *pectus* (gen. *pectoris*), the "breast"], a medicine which facilitates or causes the discharge of mucous secretions from the air-passages within the chest. Many balms, gums, and nauseating medicines, as well as demulcents and other drugs, are reputed to have expectorant properties. Some medicines not usually considered expectorant appear to stimulate the secretion of mucus in the air-passages, as the ammonium chloride (sal-ammoniac) and the potassium hypophosphite. Among the most useful expectorants are ipecac, squill, lobelia, and blood-root. These are also emetics, sedatives, and diaphoretics.

Expira'tion [Lat. *expiratio*, from *ex*, "out," and *spiro*, *spiratum*, to "breathe"], in physiology, the operation or movement by which the air that has been changed by the respiratory process is expelled from the lungs. This movement is effected partly by the elastic contraction of the lungs and the walls of the chest, which were dilated by the act of inspiration, but the resiliency of the chest-walls is greatly assisted by the action of numerous muscles, especially in forcible expiration.

Exploita'tion [from *exploiter*, to "improve," to "work"], a French term signifying the improvement of lands, the working of a mine; in general, the act of using anything as a source of profit or rendering it profitable.

Exploits, River of, traverses nearly the whole breadth of Newfoundland from S. W. to N. E. It is navigable for steamers 12 miles to the rapids, and above these small boats can go to within 50 miles of the S. W. coast. Its valley is level, well timbered, and abounds in game and fish, but has few inhabitants. This valley is recommended for colonization by the provincial government, and is believed to contain nearly all the habitable land in the interior of that large island.

Explo'sion [Lat. *explo'sio*, from *explo'do*, *explo'sum*, to "explode," "hiss off the stage or drive out"], a bursting with a loud report; in natural philosophy, the sudden and violent expansion of the parts of a body, caused by heat or chemical affinity. Explosions are often caused by the elastic force of steam confined in boilers, etc. The explosion of gunpowder is the result of the sudden formation and expansion of gases, into which the powder is converted by chemical agency. This term is also applied to the violent eruption or discharge of a volcano. Humboldt heard the explosion of Cotopaxi at the distance of 130 miles.

Explo'sives [from the Lat. *ex*, "out," and *plaudo*, to "make a burst of sound"]. Under this head will be considered the compounds practically available in war, in mining, and in general use for the sudden development of immense force. They comprise gunpowder; guncotton; Schultze powder; nitro-glycerine, with its compounds known as dynamite, or giant powder, glyoxiline, lithofracteur, and dualin; admixtures of potassium chlorate with readily oxidizable substances; and the picrate compounds. The various fulminates of mercury, silver, copper, etc., although very powerful agents, are too liable to accidental explosion for practical use, except in very small quantities, as primings for percussion-caps, fuses, etc., and they are therefore excluded from consideration.

Gunpowder, which was first employed in war about the year 1350, is the oldest and most generally useful of these agents. It is a mechanical mixture of potassium nitrate, carbon, and sulphur, in proportions usually varying but little from 75, 13, and 12 respectively. Purity is essential to excellence. The manipulations of manufacture consist, in general terms, in very finely pulverizing the ingredients, thoroughly incorporating them, compressing them into a cake, granulating it, separating the different sizes of grain by sieves, glazing, drying, and finally removing all dust by the use of fine sieves.

In the storage of gunpowder special precautions against fire and moisture are needed. A spark, friction between hard bodies, or a temperature raised suddenly to 572 degrees Fahrenheit, determines an explosion; while slight moisture, which may readily be absorbed from damp air, produces caking and deterioration. A wetting is permanently destructive to the compound. Frost produces no injurious effects, either temporary or permanent.

Being a simple mechanical mixture, the properties of gunpowder may readily be varied to suit the requirements of a quick-burning or a slow-burning explosive. Its expansive power is due to two distinct causes—the sudden transformation from a solid to a gaseous form of vastly greater volume, and the heat developed by the chemical change, which induces enormous tension. It is apparent, therefore, that a variation in the relative proportions and condition of the ingredients, by changing the chemical products of the explosion, must affect the expansive force; and also that a similar result may be obtained by mechanical means directed to modifying the duration of the time required for combustion.

It is to a skilful application of the last method that the recent improvements in gunpowder designed for heavy ordnance are due. General Rodman, of the U. S. army, inaugurated a series of experiments directed to this end in 1856, and from the results of his labors this country was provided in advance of European nations with an explosive suited to modern cannon. His mammoth and perforated-cake powders—the former consisting of large irregular grains, tested by two standard sieves of six-tenths and nine-tenths of an inch respectively, and the latter of hexagonal or cylindrical cakes perforated by holes—have been copied in the English pebble and pellet, and the Russian prismatic powders; by the aid of which the recent improvements in their artillery have been rendered possible. Pebble powder is simply pressed cake, broken into large irregular pieces and glazed. Pellet powder consists of mealed powder compressed into small blocks, of regular and sometimes indented forms, and of dimensions varying for different calibres. Prismatic powder consists of mealed powder compressed into flat, perforated cakes of hexagonal form, about an inch thick and an inch and a half on the longest diameter. This subject is still undergoing investigation; the facts having been developed that the time of burning, and hence the strain upon the gun for a given initial velocity in the projectile, may be modified by varying the size and form of the grains, their density and hardness, and the mechanical condition of the exterior.

By replacing a part of the carbon with uncarbonized peat, Mr. Oliver now manufactures a variety of gunpowder which, when well rammed, is claimed to give a higher initial velocity with a less recoil and less smoke than the ordinary grades. This advantage is attributed to slow burning.

The maximum pressure of exploded gunpowder, unrelieved by expansion, has been investigated by various parties, whose results range from 7 tons to 662 tons to the square inch, the latest authorities indicating about 40 tons.

The difficulty of obtaining saltpetre in large quantities, and hence its cost, has induced many attempts to replace it by other nitrates, such as those of sodium, lead, and barium; but although good blasting powders have been thus prepared, none suited to propelling purposes have been obtained.

Guncotton.—In 1832, Braconnet discovered that by dissolving starch in nitric acid, and adding water, a white explosive substance was precipitated, to which the name xyloidin was given. Shortly after, Pelouse obtained a similar compound by treating paper, or cotton or linen fabrics, with nitric acid, and named it pyroxilin. These were the precursors of guncotton, which was discovered by Schönbein in 1846, and at once excited much attention as a possible substitute for gunpowder. Adverse official reports, however, were soon made in France, the U. S., Germany, England, and Austria, and the explosive fell into general disfavor on account of its liability to spontaneous explosion, its corroding residua, and its excessively violent and irregular character, all of which unfitted it for most military uses. Baron von Lenk, a member of the Austrian commission, was not so readily discouraged. He continued a series of experiments for several years, which ultimately led to so great improvements in manufacture that in 1853 he was able to construct a successful twelve-pounder battery employing guncotton. This led to its temporary introduction into the Austrian military service, and again attracted the attention of foreign nations to the new explosive.

Baron von Lenk's system consisted in cleansing the long-staple variety of raw cotton in an alkaline wash, followed by one in pure water; thoroughly drying it; steeping it for forty-eight hours in a cold mixture of strong nitric and sulphuric acids—one part of the former to three parts of the latter by weight; freeing the resulting tri-nitro-cellulose from the acids by a centrifugal machine, by thorough rinsing, and finally by the action of running water for a period of six or eight weeks, alternated with a boiling potash bath and hand washing; air-drying it; rinsing it in a hot solution of potassium silicate to retard the rapidity of combustion; and, lastly, again washing and thoroughly drying it. He partially regulated the suddenness of explosion by twisting the guncotton into ropes or weaving it into cloth to secure a more uniform density. Musket cartridges were formed by wrapping the thread around wooden plugs, to prevent unequal ramming. An admixture of a certain proportion of ordinary cotton was also employed to reduce the violence of action.

In 1863, Mr. Abel, as a member of a committee appointed

by the British war office, undertook an experimental investigation into the merits of this system, and succeeded in materially improving it. Instead of the costly long-staple cotton, he employs ordinary cotton waste, which is treated with the mixed acids, one part of nitric to three of sulphuric by weight, without any preliminary process except careful drying. It is then rinsed in a large volume of water, and dried by a centrifugal apparatus three or four times. Next, it is placed in a pulping engine, like those commonly used in the manufacture of paper, and reduced to a state of fine subdivision. It is then transferred, in quantities of at least ten hundredweight, to a poaching engine, where it is beaten for about forty-eight hours until it remains uniformly suspended in a large volume of warm water, continually renewed, and finally rendered slightly alkaline. It is then dried in a centrifugal machine, and moulded into disks of the desired form and dimensions, which receive a pressure ranging from four to six tons per square inch. Up to this point the guncotton has been in a damp, and consequently entirely safe, state, and if desired it may be so stored for an indefinite period of time without losing its peculiar properties. To prepare it for use it is dried upon hot plates, freely open on every side to the air. This system of manufacture is the best now known, and yields a product so uniform and safe as to be employed in England almost to the exclusion of all the other modern explosives.

In appearance, Abel guncotton consists of regular cylinders, of dimensions varying with the use proposed. It is white in color, hard to the touch, and sinks readily in water. Ignited, unconfined, by a flame, it burns with a strong blaze. Fired by a detonating fuse, or raised to a temperature of about 340° Fahrenheit in a strong case, it explodes with great violence—a single ounce being sufficient to indent a plate of iron or disrupt a thin slab of stone upon which it is loosely laid. The character of the detonation varies with the fulminate employed, being most sudden with fulminating mercury. Even in a damp state—containing twenty per cent. of moisture—it may be exploded without much loss of power by a disk of dry guncotton in contact. It is believed, upon good grounds, to be free from danger of spontaneous explosion. The English government has adopted it as the explosive best suited to submarine warfare, and has accumulated large quantities in store.

Guncotton produces little smoke, and leaves a very small residuum of solid matter, the chief products of combustion being carbonic oxide, carbonic acid, water, and nitrogen. It is unalterable in water, no matter how long submerged. It contains about 2 per cent. of moisture in its normal condition, and even when exposed to ordinary damp air it absorbs but little more—a property which gives it a great advantage over gunpowder. Chemically, the purest guncotton may be regarded as cellulose, in which three atoms of hydrogen are replaced by three molecules of peroxide of nitrogen. Thus constituted, it is insoluble in mixtures of ether and alcohol. If, however, great care has not been observed in the manufacture, less simple compounds are formed, which may readily be dissolved in these mixtures, forming collodion, so much used in photography and the arts.

Quite recently, Punshon has succeeded in so reducing the quickness of action of guncotton by mixing with it nitre and crystals of cane-sugar as to make it well suited for use in small-arms. Indeed, the present subject for investigation in connection with guncotton appears to be the admixture with it of some oxidizing agent, such as potassium or sodium nitrate; experiments have indicated that an increase of power may thus be gained.

Schultze Powder.—The conversion of lignin or wood-fibre into an explosive similar to guncotton was attempted soon after the discovery of that compound, especially by Captain Schultze, acting for the Prussian government. His method consisted in soaking the wood—preferably alder—in water, to give it toughness; cutting it by fine saws into a kind of cross-grained veneering; and subsequently punching it into small cubes, of which the size varied with the use for which the powder was designed. The grains thus produced were boiled in a solution of soda, and afterwards alternately exposed to steam and washed in a solution of chlorine to free them from resins, etc. They were next treated for several hours with mixed nitric and sulphuric acids, kept cool by constant stirring, and afterwards were thoroughly washed and dried. In this state the powder is but slightly explosive, and it may be kept in store indefinitely. For use, the grains must be submerged for about twenty minutes in a solution of nitrate of potassa and baryta, and then carefully dried and sifted. The necessary oxygen having been now supplied, the powder has a high explosive power. It burns with but little solid residuum or smoke, and is said to be both cheaper and stronger than common gunpowder, weight for weight. It, however, readily attracts moisture, is liable to form dust by attrition, and is more bulky than gunpowder, in the proportion of 3 to 1.

Nitro-glycerine or *glonoin oil* was discovered in 1847 by Ascagne Sobrero, but remained unapplied to practical uses until 1864, when Alfred Nobel, a Swedish engineer, began to develop its industrial value. Since then it has been largely employed upon the continents of Europe and America. It is prepared by the action of a mixture of concentrated nitric and sulphuric acids upon glycerine introduced drop by drop. At ordinary temperatures it is an oily liquid, usually colorless if made from good glycerine, but sometimes discolored by causes not well understood. It has no odor, and is of a sweet and slightly pungent taste. It is highly poisonous, even short contact with the skin being sufficient to produce severe headache. Its specific gravity is 1.6. When first made it has a milky appearance, which ultimately disappears. Nitro-glycerine incompletely freed from the acids undergoes spontaneous decomposition, is dangerous to handle, and ultimately may lose its explosive properties. When pure it congeals at from 40° to 45° Fahrenheit, and is then nearly or quite incapable of explosion. At 212° Fahrenheit it begins to decompose; at 365° Fahrenheit it throws off yellow or reddish fumes; at 423° Fahrenheit it deflagrates violently. When uncongealed, nitro-glycerine may readily be exploded by concussion, which renders it quite unfit for transportation in that state. In store it should be kept in a cool place, under pure water, in open vessels, and, if practicable, in a frozen condition. For use, it should be thawed very gradually, by placing the can in warm water raised to a temperature not exceeding blood heat. Any leakage should be carefully avoided at all times, and emptied cans should be destroyed. Flame applied to small quantities of nitro-glycerine causes it to burn with difficulty like ordinary oil, but a fulminate exploded in contact with it produces a tremendous detonation. To develop its full effect, fulminating mercury, in quantities not less than fifteen Troy grains, and confined in a strong copper capsule, is recommended. Its advantages as an explosive consist in its instantaneous development of force, due to the fact that, pound for pound, it produces at least three and a half times as much gas, and twice as much heat, as gunpowder; its high specific gravity, which permits the use of small drill holes; its admitting of water, or loose clay, or even air, tamping; and finally, the facility with which it can be made upon the spot for immediate use. Its disadvantages are the severe headaches it causes to those not habituated to its use, its liability to spontaneous explosion, the dangers sure to attend its careless handling, and, especially for military uses, its unfitness for being kept long on hand, unless prepared and treated with a degree of care not readily to be secured. To these may be added the fact that its rate of explosion is not under control, which restricts its economical use to blasting in hard rock or under water. In soft rock or clay its power at equal cost is inferior to that of common gunpowder, because its action is akin to a sudden blow, rather than to a continued push.

Dynamite, called in the United States "giant powder," was invented in 1866–67 by Nobel; it consists of nitro-glycerine absorbed by some porous inert solid. The percentage of the former is of course limited by the capacity of the absorbent. The best material is a silicious infusorial earth found in Hanover, and known as *kieselguhr*. It is when dried a white, impalpable powder, showing under the microscope a cellular structure. It will absorb and safely retain three times its weight of nitro-glycerine. Many experiments were made in Paris during the late siege to discover the most suitable substitute there available. Finally, a residue from the gas-works was adopted, which would take up and retain a little more than its own weight of nitro-glycerine.

Dynamite made from kieselguhr has the appearance and consistence of heavy brown sugar. It possesses most of the virtues of the parent nitro-glycerine, with some peculiar to itself; of which the chief are, exemption from liability to spontaneous explosion and to detonation from moderate shocks, both of which result from the exceedingly fine granulation of the nitro-glycerine. It has been very largely used in this country, especially in California, and these important advantages are now generally admitted. Dynamite possesses another decided advantage over nitro-glycerine. If kept in the state of loose powder without compression into cartridges, it may be exposed to any natural temperature without losing its explosive properties when subjected to the action of a primer charged with fifteen grains of fulminating mercury; and this too without becoming more sensitive to ordinary shocks and handling. In the form of compressed cartridges it is as inexplosive when thoroughly frozen as nitro-glycerine itself. Saturated with water, it loses only a very small percentage of its explosive power, but requires a primer much more powerful than those ordinarily used. Ignited by a flame, and unconfined, it burns quietly without detonation. Experiment indicates that its explosive force is not quite so instantaneous as that of pure

nitro-glycerine; hence, in certain kinds of resisting media, where a sustained pressure is required, the mechanical work performed by three-quarters of a pound of nitro-glycerine in the form of dynamite may largely exceed that produced by a full pound of the unabsorbed material. This apparent paradox actually occurs in submarine mines, usually called torpedoes. For rock-blasting, dynamite should be pressed firmly home and tamped with sand.

Dynamite possesses another merit. By combining its ingredients in judicious percentages, a certain control can be exerted over the quickness of its action, and a classification similar to that of the different grades of gunpowder, but much more restricted in range, may be made.

Various have been the attempts to improve upon dynamite by replacing its inert base with different explosive materials. Of such compounds, glyoxiline, lithofracteur, and dualin are the best known; but none of them are believed to be improvements for rock-blasting, chiefly for the reason that the bulk is increased in a higher ratio than the power, and hence, as the cost is largely dependent upon the size of the drill-holes, no real economic gain is made.

Glyoxiline was invented by Abel shortly after the introduction of dynamite. It consisted of a mixture of gun-cotton pulp and potassium nitrate, saturated with nitro-glycerine, and was made both in a granular and a cake form. It proved to be less troublesome in handling, owing to the granules being coated with an impermeable material which reduced the tendency to produce headache, but it was never largely introduced into practical use.

Lithofracteur was devised about the same time by Prof. Engels of Cologne. Its precise composition is not made public, further than that it consists of 525 parts of nitro-glycerine, 225 parts of silica, and 250 parts of mineral bodies; and analyses of different samples have exhibited varying results. One authority (Trauzl) reports 52 parts of nitro-glycerine, 30 parts of kieselguhr, 12 parts of coal, 4 parts of sodium nitrate, and 2 parts of sulphur. Others place the proportion of sodium nitrate as high as 25 per cent.; others add guncotton. Lithofracteur is a pasty substance of dark color. Like the other compounds of nitro-glycerine, it burns quietly when ignited by a flame, and explodes violently when fired by a detonating fuse. Water dissolves the sodium nitrate, and thus sets free a certain part of the nitro-glycerine—of course a decided disadvantage. The compound exhibits explosive properties similar to dynamite, and offers equal security against concussion. Its use heretofore has been restricted chiefly to Germany and Belgium, although it has been experimentally tried in England, and was employed by the Germans in the late war with France.

Dualin was invented by Dittmar shortly after dynamite, and its use has been chiefly restricted to Germany and the U. S. The patent describes it as consisting of "cellulose, nitro-cellulose, nitro-starch, nitro-mannite, and nitro-glycerine, mixed in different combinations, depending on the degree of strength which it is desired the powder should possess in adapting its use to various purposes." A sample supplied by the inventor for trial at the Hoosac Tunnel was found by analysis to consist of 60 per cent. of nitro-glycerine and 40 per cent. of washed sawdust, not treated with nitric and sulphuric acids. Trauzl reports it as consisting of 50 parts of nitro-glycerine, 30 parts of fine sawdust, and 20 parts of potassium nitrate. The best variety now manufactured is believed to be cellulose derived from poplar pulp, treated with nitric and sulphuric acids, and saturated with nitro-glycerine.

Having a less specific gravity than dynamite, dualin is slightly inferior to it, bulk for bulk, in explosive energy. When thoroughly soaked in water, it can only be exploded by a very violent detonation, much exceeding that of the ordinary fuse, and even then it loses more than half its power. It congeals at about 45° Fahrenheit, and in this state readily explodes, becoming so sensitive to friction as to make it dangerous to tamp in cold weather. In other respects its properties resemble those of dynamite.

The Chlorates.—The violent action of potassium chlorate upon readily oxidizable substances has given rise to many attempts to employ it in the preparation of substitutes for gunpowder. Under the names of white gunpowder and German gunpowder a mixture of this salt with potassium ferro and ferri-cyanide and sugar has long been known. Mixed with nut-galls, resins, and other vegetable substances, it has been repeatedly introduced to temporary use as Horsley's powder, Ehrhardt's powder, etc. The form best known in this country consists of potassium chlorate, potassium nitrate, and crude gamboge, which, under the name of Oriental powder, or safety compound of the Oriental Powder Company, was at one time considerably employed in the oil-wells of Pennsylvania and for other blasting purposes. Its dangerous sensibility to friction, and the consolidating effect of heat upon the gum, have prevented its general use. With some of these chlorate compounds sulphur enters as an ingredient, which intensifies the chief objection against them—their liability to explode from slight friction or percussion. As a class, they have many times the explosive intensity of gunpowder, but are also more dangerous to handle. For special purposes they are extremely useful—for instance, a mixture of potassium chlorate and sulphur, formed into a paste, and dried to fit small cartridge-cases of lead, has been found to be terribly effective as a charge for explosive bullets. They may be fired with safety from a musket, but explode with great violence, even in penetrating flesh.

The Picrates.—Picric acid was discovered in 1788 by Haussman while treating indigo with concentrated nitric acid. Within a few years chemists have derived it from other substances, especially from carbolic acid. It has been called *amer d'indigo*, *amer de Welter*, carbo-nitric acid, nitro-picric acid, carbazotic acid, and tri-nitro-carbolic acid. It is a crystalline body of a brilliant golden yellow, very bitter to the taste, and is largely used as a dye. When heated to 600° Fahrenheit it detonates with violence.

The salts obtained by treating many of the bases with picric acid possess its characteristic properties; that best known is the potassium picrate. This forms golden crystals having a metallic reflection. Insoluble in alcohol, and but slightly soluble in water, it detonates violently at 600° Fahrenheit. Its action is akin to that of the fulminates in suddenness; and to regulate this property, Designolle has mixed it with charcoal and potassium nitrate, thus forming a compound similar to, but more powerful than, ordinary gunpowder. To obtain the maximum explosive energy, he employs equal parts of potassium nitrate and potassium picrate. For use in rifles from 12 to 20 per cent. of potassium picrate is used, with a small amount of charcoal. For cannon only from 8 to 12 per cent. of potassium picrate is employed. Under the name of *poudre Designolle* this compound has been considerably manufactured in France for military purposes, both for large guns and for torpedoes.

Brugière powder consists of an admixture of ammonium picrate and saltpetre. It is comparatively a slow powder, less liable to attract moisture than ordinary gunpowder, and yielding but little smoke. In England, Abel has experimented with a similar compound, to which he has given the name of picric powder, and which he considers especially suited for use in shells, because, although little liable to explode from concussion or friction—the great objection to the potassium picrate compounds—its effects when strongly confined are more violent than those of gunpowder.

H. L. Abbott, *U. S. Army.*

Expo'nent [Lat. *expo'nens*, from *ex*, "out," "forth," and *pono*, to "put," to "set"], literally "setting forth" or indicating; hence an index or representative; in algebra, a number or symbol representing a number which, when written above and at the right hand of any symbol of quantity, indicates a corresponding power of that quantity. Thus a^3 denotes the *third power of* a, and 3 is said to be the *exponent* or index of that power; usually, though less correctly, it is called the exponent of a. Thus a^2 is merely an abbreviation of aa, and from the definition of an exponent it follows at once that $a^{m+n} = a^m a^n$. The notation of exponents was introduced by Descartes, and being very convenient was soon extended. The convention on which the extension is based is the general truth of the above equation. Thus, if we ask for the meaning of a negative or fractional exponent, on the hypothesis that the above equation shall hold for all values of m and n, we find that since $a^m = a^{m+0} = a^m a^0$, a^0 must be a symbol for 1, no matter what a represents.

Exponen'tial Equa'tion is one involving terms wherein the unknown quantity is an exponent or constituent of an exponent. The simplest form of such an equation is $a^x = b$; one of its solutions is the logarithm of b to the base a, or, what is the same thing, the ratio of the logarithm of b to that of a, the bases being the same, but arbitrary. This is one solution only; the equation has many other imaginary roots, and is consequently transcendental. A curve in whose equation the co-ordinates appear as exponents is also called an exponential curve. The logarithmic curve is an example.

Exports. See Commerce, by J. S. Gibbons.

Exposi'tion, Interna'tional and Univer'sal, a name applied to the great public exhibitions which have been held, within the last twenty-five years, in various countries, of the products of the industry and of the evidences of culture, intellectual and æsthetic, of all nations; notably, to those of London in 1851 and 1862; to those of Paris in 1855 and 1867; and to that of Vienna of the present year (1873). These grand displays may be regarded as the development on the largest scale of an idea which, for the preceding fifty or sixty years, had had many

less imposing manifestations—the idea that, in order to the improvement of the arts of industry, the first requisite and the most effectual incitement is to be found in acquainting a people with the actual state of those arts as they exist. These expositions, therefore, though nominally universal, comprehended in their first conception and in their earliest practical illustrations only what are called the useful arts, in contradistinction to the liberal and the fine arts; and they furthermore omitted from their scheme the evidences of that kind of moral activity among peoples, which aims to ameliorate the condition of the human race by repressing vice and crime, by relieving distress, by diminishing the amount of disease, by the improvement of prison discipline, by softening the horrors of war, and by other means analogous to these; all of which have been kept more or less in view in the later. The early international expositions, moreover, omitted to provide, or at least provided only on a limited scale, for the display of animals useful to man, or of living and growing vegetables, plants and flowers, or for illustrating the operations of the garden, the field, the farm, and the dairy. The later have given to these objects a very large portion of their space.

Public exhibitions of the products of industry were in the first instance held as marts or fairs. (See FAIRS.) The earliest held not for commercial purposes, but strictly for the promotion of improvements in the useful arts, were instituted by the Society of Arts of London. This society has held such exhibitions annually since 1760. The first properly national exhibition of this kind, the first that is to say organized under government direction, took place in France in 1798. Since that time, the French government has given a similar exhibition every four or five years. The effect has been greatly to improve the quality and to enlarge the quantity of production in all the departments of industry throughout France. "The French writers," says Judge Daly (*Address before the Am. Inst.*, 1863), "attribute the wonderful progress of French industry to four causes: 1, the diffusion of knowledge, scientific and practical, among the working classes, through the establishment of free local libraries, museums, drawing-schools, and other means of practical instruction; 2d, inventions and discoveries; 3d, the repeal of restrictive laws; and lastly, the effect of the great industrial exhibitions. The effect of these exhibitions may be briefly stated. They have focalized the industry of the country, by bringing it under view as one spectacle, thus enabling all to know from time to time, the exact state of it. They have afforded means of comparison which did not previously exist, not only to those engaged in a particular pursuit, but also to those employed in those pursuits which act reciprocally upon each other. They have created a mutual interest between the man of science, the manufacturer, the capitalist, and the working classes. The intelligent criticism to which they have given rise in the various industrial journals, not only from scientific men but from manufacturers and workmen, has been of the greatest benefit. Their regular recurrence has kept up a spirit of emulation, in the desire to produce something better and cheaper than before. They have served as a means of advertising new or superior productions, upon a scale the most extensive; and have led to the gradual development of the business theory of large sales with small profits. They have stimulated inventions, by keeping up the constant desire for new discoveries, improved methods, and better machinery; and lastly they have dignified labor by giving it something more to struggle for than mere pecuniary compensation."

In the United States, since early in the present century, exhibitions for the encouragement of agricultural or mechanical industry have been annually held under State and county organizations, with partial aid from the State governments, in some States of the Union, and more recently in many. The Franklin Institute, founded in 1824, in Philadelphia, the American Institute established four years later in New York, and many less conspicuous though perhaps not less useful associations organized for promoting industrial improvement, have relied on public exhibitions as among the most effectual means of accomplishing their objects.

Of international expositions, the first in the series, that of 1851 in London, was undertaken at the suggestion, and successfully carried out through the influence, of Prince Albert, who was at that time the president of the London Society of Arts. A building was erected in Hyde Park for the accommodation of the objects entered for exhibition, upon a design of an entirely novel and original character proposed by Joseph (afterwards Sir Joseph) Paxton, a landscape gardener, at that time in charge of the gardens of the duke of Devonshire at Chatsworth. The materials employed were almost exclusively iron and glass, whence the structure received the name of "the crystal palace," a name which has been applied to other similar constructions since. The plan was a long rectangle with a transept crossing the centre, the whole covering an area of more than twenty acres of ground. In the contract for the erection of the building it was stipulated that, at the close of the exhibition, it should remain the property of the contractors, which stipulation reduced the cost to the commissioners by £100,000 or half a million of dollars. The total cost for building, maintenance, superintendence, recompenses to exhibitors, legal expenses, etc. etc., was about £293,000. The total receipts from all sources were £506,000, showing that the exhibition, apart from the large and permanent indirect benefits accruing from it, was a direct financial success. This cannot be said of any of those which have succeeded it.

The universal admiration attracted by the exposition of 1851 and its brilliant results, stimulated a similar undertaking, two years later, in New York. The short intervening time allowed for preparation, and the distance of the place of exhibition from the countries most advanced in manufactures and other productive arts, suggested a large reduction in the scale of the display. The location selected was a public square, 445 feet by 455 feet only in dimensions, or about 4¾ acres. Upon this a "crystal palace" was erected octagonal in ground plan, but having above two naves intersecting symmetrically at right angles, each 365 feet 5 inches by 149 feet 5 inches. The intersection was crowned by a hemispherical dome, 100 feet in diameter, the height of the springing line being 70 feet, and the total height to the summit above the crown 123 feet. In order to increase the extent of floor surface for the purposes of the exhibition, spacious galleries were constructed in the arms of the building, the total surface thus secured amounting to 250,000 square feet or 5¾ acres. The cost of the building was about $200,000, to defray which and to maintain the exhibition, money was raised by an issue of stock, at first to $300,000, afterwards increased to $500,000, in shares of $100 each. These shares soon rose in value, and they were at one time at a premium of 75 per cent. The enterprise nevertheless resulted in loss, the destruction of the building by fire a few years later having finally destroyed all prospect of redeeming its fortunes.

During the same year, 1853, a similar international exhibition was held in Dublin, in a building forming a series of parallel halls. The cost was £80,000; the receipts, £47,000.

The Paris International Exposition of 1855 was in effect a private enterprise, but it was conducted by a commission appointed by the government, who also undertook to secure it against loss. The principal building on this occasion was erected of masonry in the Champs Elysées. The great hall devoted to the exposition was lighted from the roof. This building provided an extent of 1,770,000 square feet of floor surface to the industrial departments not employing machinery in motion. The machinery was established in an "annex" on the bank of the Seine, four thousand feet long. The fine arts were provided for in another building; and the tapestries and carpets of the imperial establishments, as well as the crown jewels, in still another. This exposition cost 11,264,520 francs = $2,253,000, not including the cost of the main building, which was preserved as the property of the government, under the name of the "Palais de l'Industrie," to be used for annual exhibitions of various kinds and for public ceremonials.

The second London Universal Exposition was held in 1862. For this, the location chosen was upon a ground which had been purchased at South Kensington by the commissioners of the exposition of 1851, with the surplus proceeds of that exposition and some aid from the government. The principal building was nearly rectangular, and covered about seven acres. The whole area covered by roofs was about twenty-three acres. The buildings were subsequently removed, the space occupied by them being required for government purposes, and the principal one was transferred to the north of London, where, under the name of the Alexandra Palace, it was totally destroyed by fire in June, 1873.

The international exposition of 1867 at Paris was the most comprehensive in its plan, the most elaborate in its preparations, and the most colossal in its dimensions, of all which had been held up to that time. The government announced its intention four years in advance. In June, 1865, an imperial decree created a commission to direct the work, under the presidency of Prince Napoleon, who shortly after resigned, and was replaced, in February, 1866, by the Prince Imperial. The place fixed upon for the principal exhibition was the Champ de Mars, the large parade-ground in front of the *École Militaire*, containing about 111 acres. For the exhibition of farm and dairy operations, animals and stock, the island of Billancourt in the Seine, two and a half miles from the Champ de Mars, was chosen, having an area of 74 acres. For the competitive trials of mowers and reapers and other field operations,

portions of the emperor's farms at Fouilleuse near St. Cloud, and of those at Vincennes, were given up as occasion required. The margin of the Seine in front of the Champ de Mars (from which it is separated by the quay D'Orsay) offering an area of about three acres, was devoted to objects connected with navigation, to diving apparatus, and to machinery for raising water. Here also was found a convenient place for a chemical laboratory in which experimental lectures were delivered during the exposition. The principal exposition building was constructed mainly of iron, and was of enormous dimensions. The entire space enclosed within its exterior walls was 36 acres, but there was an open central court of about one acre in the centre. This building occupied the centre of the Champ de Mars. The surrounding area was called the park, and was allotted to the different countries represented in the exposition, for the construction of buildings to accommodate objects or to facilitate operations which could not be allowed in the main building, or to illustrate the characteristic domestic or school architecture of different peoples; or for more imposing structures representing the temples and palaces of pre-historic antiquity. The entire area of the park was about 75 acres; but of this, 12½ acres, in the south-eastern angle, were cut off from the rest by an enclosure, and devoted to a horticultural and botanical exhibition under the name of the Reserved Garden. The park and the garden, as well as the farming and agricultural exhibitions at Billancourt, were new features in these great undertakings; and to many visitors the two former were quite as attractive as the display within the palace, or even more so. The whole area was laid out with much taste, the grassplots, always vividly green, being intersected by winding walks with here and there a limpid stream, the various buildings erected without any obvious order presenting an endless variety of aspects from different points of view. In the reserved garden, an immense structure of glass occupying an artificial eminence protected a magnificent collection of tropical trees and plants, while the shrubbery of all the forests of Europe covered the side slopes. Two huge aquaria also, within this same enclosure, presented specimens of the most remarkable and the most interesting inhabitants of the ocean and of inland waters. The construction of these was such that the spectator as he advanced found himself in a cavern beneath the surface of the water, through the glazed roof of which he saw the animals sporting above his head, while they were at the same time around him on every side.

The principal building, or so called palace, was constructed without any attempt at architectural effect, but with the design to make as conspicuous as possible the method of arrangement with reference to the plan of classification by correlated groups of objects, and by countries; and so to facilitate to the visitor the study of the exhibition and to enable him readily to find any particular object sought. It had the form of an ellipse with flattened sides, or more properly of a parallelogram with circular ends, the extreme length being 490 mètres, or 1607.64 feet, and the extreme breadth 380 mètres, or 1246.74 feet. The entire cost of the structure, including the necessary excavations and other earthworks, was about 11,785,000 francs = $2,357,000. During the last six months of 1866, there were employed in the Champ de Mars, principally upon the palace, 1477 workmen.

In plan, the palace was divided into seven concentric halls, or galleries, corresponding to seven of the ten groups in the scheme of classification. The other three groups embracing live stock, agricultural exhibitions, etc., could not be introduced into the building. These halls were intersected by radial lines, forming boundaries between the spaces allotted to the different countries. This plan had the apparent disadvantage of allotting to every country the same proportionate space for the several groups; while in these several groups different countries are differently prolific. This disadvantage, however, was got over by allowing departures when necessary from the regularity of the elliptical divisions, without, however, allowing the elliptical passages, or promenades, to be interfered with. Sixteen of the radial divisions were formed by open passages, the principal entrance, on the main axis, being 15 mètres, or 49¼ feet wide; the opposite one, at the other extremity of this axis, 10 mètres, or 32.81 feet; which latter breadth was also given to the passages corresponding to the minor axis. Besides these, there were 12 other radial passages, 5 mètres, or 16.41 feet wide. The gallery of the fine arts, which formed the inner hall, though divided by partitions to mark the countries, afforded, through large open doors, an unobstructed passage around the whole ellipse; and the same was true of the gallery of machinery which was outermost. There were, besides these, three other perfectly free concentric passages, of 5 mètres, or 16.41 feet each, making the complete circuit of the building. A verandah roof exterior to the main building surrounded it entirely, sheltering a "gallery of aliments," or series of restaurants, characteristic of different countries, 10 mètres = 32.81 feet broad, and also a colonnade 5 mètres = 16.41 feet wide, beyond this. As an afterthought, an additional gallery was introduced into the plan, during the construction of the building, inside the gallery of the fine arts, 8½ mètres = 27.9 feet wide, within which still was a sheltered promenade 5.65 mètres = 18.55 feet wide, and within that the central court, adorned with fountains and flowers. Finally, in the midst of this court, stood a beautiful pavilion, where there were exhibited the standard weights and measures of all nations, and all their varieties of coins. Surmounting the dome of this pavilion was a large artificial globe, with its axis parallel to the axis of the earth, which, being driven by clockwork, revolved like the earth once in the twenty-four hours.

The park, besides the objects which have been mentioned above, contained "annexes" in which were exhibited objects which might be called the overflow of the palace—the space allowed the exhibitors within the buildings not sufficing for their purposes. Thus, here were seen the most magnificent displays of galvanoplastic work, of photographic enamelling for stained-glass windows, of costly India shawls, etc. etc. Here also were seen objects not enumerated in the original scheme, especially ordnance and the material of war generally; first-class lighthouses of full dimensions; the ambulances and other apparatus of the American Sanitary Commission, and of similar associations in other countries; objects gathered by Christian missions among savage nations, with specimens of the publications of missionary societies in all languages; a complete model in relief of the valley of the Nile; a diorama showing the Suez ship-canal throughout its whole length, with models of the machines employed in its construction, and others illustrating the system of traction, by which vessels are conducted through it from sea to sea. These are only examples of a very numerous and miscellaneous class of exhibitions of high interest, which found their place in the park.

The total expense of the exposition on all accounts, from the beginning to the final liquidation, amounted to 22,983,817.99 francs = $4,596,764. The total return produced by the exposition was only 14,114,662.09 francs = $2,822,900; but there was a "subvention" of 6,000,000 by the government, and another of like amount from the city of Paris, making the total receipts 26,114,662.09 francs; giving an excess of 3,130,844.10 francs = $626,000 above expenditure.

The number of exhibitors, visitors, jurors and awards at each of the four great international expositions as yet held, is presented in the following summary:

Year.	Place.	No. of Exhibitors.	No. of Visitors.	No. of Jurors.	No. of Awards.
1851	London...	15,500	6,039,195	318	5,248
1855	Paris.....	23,954	5,162,330	398	11,073
1862	London...	28,653	6,225,000	620	13,423
1867	Paris.....	52,200	9,238,967	693	19,776

The awards in every instance include *honorable mentions* as well as the more substantial recompenses. The number of honorable mentions has usually been something less than half the entire total. The number of visitors as given for 1867, embraces only the paying visitors, and includes the subscribers for the season or for various lengths of time from a week upward, 95,688 in all, only once each; whereas the holders of subscription tickets probably used them many times. Moreover, the exhibitors and their assistants, the employés of the administration, the foreign commissioners, the jurors, and the royal and imperial visitors, entered free. From calculations made by the imperial commissioners in their final report, it appears that the actual number of admissions to the exposition during its continuance, including repeated admissions of the same person, was 15,000,000, or upwards, and the average number of admissions daily was nearly 70,000. The total number of exhibitors given above (52,200) includes 381 entries made by different sovereigns and governments, which, not being designed for competition, should be deducted. Curiously enough, the French final report includes these entries "*hors concours*" among the awards. They should be deducted on both sides, when the result will be, exhibitors, 51,819; awards, 19,395, of which the distribution among the principal countries is as follows: France 15,804 exhibitors, 9938 awards; U. S. of America, 536 exhibitors, 291 awards; Holland, 587 exhibitors, 198 awards; Bavaria, 404 exhibitors, 183 awards; Belgium, 1909 exhibitors, 972 awards; Prussia and North Germany, 2447 exhibitors, 1132 awards; Austria, 2018 exhibitors, 1035 awards; Switzerland, 1001 exhibitors, 351 awards; Spain, 2636 exhibitors, 509 awards; Portugal, 1881 exhibitors, 268 awards; Sweden and Norway, 1077 exhibitors, 323 awards; Italy, 4144 exhibitors, 795 awards; Turkey, 4196

exhibitors, 134 awards; Brazil, 1336 exhibitors, 97 awards; Great Britain, 6032 exhibitors, 1702 awards.

The management of a great international exposition is an undertaking which exacts for its success the exercise of administrative and executive ability of the highest order. The difficulties which attend the task are peculiar. A formidable one, which presents itself in the very beginning, is the selection of a suitable site. So vast has been the scale which the more recent exhibitions of this kind have spontaneously taken, as illustrated at Paris, and in the exposition now in progress at Vienna, that no open areas adequate to their purposes can any longer be looked for in the interior of large cities. Yet it is only in presence of large cities that such expositions can exist; for the great multitude of exhibitors and visitors whom they invite must have the accommodations which only such cities can furnish. If not held in cities, therefore, they must be held in the immediate vicinity of cities, and in situations easy of access from them. The site must also lie upon some great line of transportation, or better at the point of convergence of many such lines; and if possible it should be approachable for vessels of burden by water. The next difficulty arises out of the necessity of improvising structures of great magnitude and of very substantial character, for the accommodation of the objects to be exhibited, in very brief time. The preparation of suitable grounds, also, is sometimes a work of almost equal magnitude. In the Champ de Mars, for example, one hundred and twenty acres of arid sand were converted into a lovely landscape garden in a single season. In the preparation of these buildings and grounds, moreover, provision must be made for thorough ventilation, drainage, water supply, and gas lighting, on a scale to meet the wants of fifty thousand people constantly, and the occasional wants of more than twice as many. The hydraulic service must be ample, so as to meet at once and effectually any danger from fire; and it should have a head above the level of the highest buildings. There must furthermore be a watchful and intelligent sanitary service, not only to afford relief in case of accident or sudden illness among the assembled multitudes, but also to guard against the first possible approaches of epidemic. The daily care of the buildings and grounds, for purposes merely of security and cleanliness, requires the employment and constant supervision of an army of inferior employés; and to all these provisions must be added that of an efficient police, subject to the direction of the managers of the exposition. The installation of the objects to be exhibited is another task of immense magnitude, of which the difficulty is enormously enhanced, not only by the brevity of the time allowed in which to accomplish it, but on account of the almost endless multiplicity of details which it involves. Compared with this, to move the material of an army of a hundred thousand men is a work of comparative simplicity; for in that case the material, though cumbrous, is in great homogeneous masses, the masses are limited in variety, and the sources from which supplies are to be drawn are few and generally known. In the case of the exposition, the material to be received and disposed of is almost infinite in variety, and it comes in an endless number of independent parcels. All these parcels, to the extent of many thousands of tons, arriving almost simultaneously, render the regulation of the system of transportation and of installation, a task exceedingly perplexing. Many of the objects, especially the machines, are so cumbrous as to require foundations of masonry to be provided for them; and these require excavations; all which work has to be done for all nations within the space of a few weeks. The arrangements necessary for the supply of motive-power to the machines, it being consistent neither with safety nor with comfort to allow powerful engines with their furnaces and boilers within the building, add another element to the complication; so, that, taking all things into consideration, the punctuality with which the great expositions have been hitherto opened on the days originally appointed, is evidence that they have been ably and efficiently directed; notwithstanding that here and there exhibitors have been caught unprepared. In regard to these accidents, it must be borne in mind that the chief commissioners have no such absolute control over exhibitors as a general has over his troops; and that they cannot always force the laggards who have once secured their places, to complete their arrangements with the promptness demanded.

Since the exposition of 1867, the question has been somewhat discussed whether the advantages secured by displays so ephemeral, on a scale so gigantic, are sufficient to compensate for the great labor, expense, loss of time and temporary locking up of capital, which necessarily attend them. The benefits are undeniably great, but it is just as they are beginning to be really felt, that the whole scene disappears. To study and understand a display of such magnitude, is a task which may occupy the clearest mind for weeks or months. The opportunity is lost just as the visitor who comes to learn is beginning to profit by it. The imperial commissioners of 1867, therefore, in their final report, express, very decidedly, their opinion, that hereafter, temporary expositions should no more be encouraged; but that permanent museums of industry should be established in large capitals, or in their neighborhood, embodying and even improving upon the best features of those great industrial displays which have gone before; and keeping constantly under the eyes of all mankind everything which may serve in any manner as an indication of the existing state of the world's civilization. Of course, to sustain such permanent museums, the commercial feature must enter in. The commissioners believe that such a modification is practicable, and that it will be advantageous to the industrial interests of the capitals where such museums shall be established. The experience to be acquired at the exposition of the present year (1873) at Vienna, and at the centennial exposition of the U. S. at Philadelphia in 1876, may throw some additional light upon this question. Meantime a company in New York has obtained a charter from the legislature for the establishment of a permanent industrial exposition in that city; and it is possible that an experiment upon such a plan may be there tried. F. A. P. Barnard.

Exposition, The International Universal, at Vienna, Austria, 1873, was opened on the first day of May and closed on the third day of November. The attention of the Austrian people appears to have been directed towards holding a great exhibition some time before the Paris Exposition of 1867 was projected, but the attempt to realize their wishes in the fullest degree was postponed in favor of the French enterprise. An exhibition of considerable pretensions was, however, held in the year 1866, under the auspices of the government, through the department of agriculture and forestry. The Prater was the locality. It was opened on the 17th of May, and closed on the 14th of June. Its duration appears to have been cut short by the war with Prussia. The first proposition to hold a great international exhibition at Vienna in the year 1873 is said to have proceeded from the Trades' Union of the city, a very wealthy and influential organization, with Baron Wertheimer, a safe-manufacturer, at its head.

It was supposed that it could be so carried out that the receipts would nearly cover the expenditures; at any rate, it was decided that a guarantee-fund of 3,000,000 florins would be sufficient to cover all possible deficiencies, and subscriptions to this amount having been obtained, chiefly among members of the society, the government was induced to take an active part in the matter, and to announce, May 24, 1870, by an imperial and royal decree, "that, under the august patronage of His Imperial and Royal Majesty the emperor, an international exhibition will be held at Vienna in the year 1873, having for its aim to represent the present state of modern civilization and the entire sphere of national economy, and to promote its further development and progress." The enterprise was thus from the outset under the immediate patronage and control of the imperial government. It had not only its sanction, but its heartiest sympathy and support, and it was finally sustained by government appropriations.

An imperial commission was named, consisting of 175 members, selected from the chief officers of the departments of the government, and from the leading men of science, art, and industry in the empire, especially of those who had taken part in former international exhibitions as members of the commissions or as jurors, delegates, or reporters, and who had gained honor and distinction in their respective spheres of duty. The archduke Charles Louis was named as the protector, and the archduke Regnier the president.

By the imperial decree of the 29th Sept., 1871, the whole direction, administration, and carrying out of the exhibition, as also by private imperial letter and decree of Jan. 9 of the same year, were conferred upon the privy counsellor Dr. William Baron von Schwarz-Senborn, as administrator of the exhibition, with the title of the Imperial and Royal General Director. To a high and just appreciation of the functions of great international exhibitions, and of their importance to nations and civilization, the baron added great experience in their organization and management by his official connection with them as commissioner of the Austrian government in London in the years 1851 and 1862, and in Paris in 1867. All the imperial and royal authorities were obliged in their intercourse with the general director to assist him as much and as promptly as possible. A regiment of sappers and miners was detailed for duty in the exhibition grounds, and not only assisted in the construction, but in guarding the buildings after the opening.

The location selected was the famous Prater, the park

and place of resort of the Viennese, lying about one and a half miles from the centre of the city, and between it and the Danube. It was also in the immediate vicinity of the great engineering work undertaken for the regulation of the flow of that river. The surface consisted of the almost level alluvion of the river, and was raised in some portions by the addition of about four feet of gravel dredged from the river-bed.

About 280 acres, or 1,131,235 square mètres, were enclosed by a high board fence. The extreme length of the tract, approximately a rectangle in form, extending E. and W., was about 1400 mètres, and the width 720 mètres. The total length of the fencing was about 4500 mètres, or 14,763 feet.

The principal buildings, all of one story and without galleries, were the Industry Palace, Machinery Hall, Art Buildings, and Agricultural Halls, ranged side by side in three zones. The total length of the Industry Palace was about 3000 feet, and its floor-area, exclusive of the courts, 78,328 square mètres, or 19.35 acres. It consisted of one main transept, crossed by sixteen galleries, giving thirty-two arms or wings, each 75 mètres long by 25 mètres wide. Between these galleries there were open courts, most of which were roofed over to gain additional space. The rotunda, rising in the centre of the transept, was the chief architectural feature of the exhibition; it was designed by Mr. Scott Russell, and constructed of wrought iron. It is a flat truncated cone, with a pitch or slope of about 31°; a diameter to the edge of the base of 354 feet 8 inches, and is supported on thirty-two wrought-iron columns 24.4 mètres high. The interior height to the base of the large lantern is 158 feet, and to the top of the crown 276 feet. It cost $500,000. (For dimensions and form, as compared with St. Peter's and other domes, see ROTUNDA.) The plan of the Machinery Hall was a simple rectangle, 2620 feet long and 165 feet wide, covering an area of 9 acres. The Fine Art Gallery afforded 30,800 feet of wall-length, and covered 1½ acres; the three agricultural buildings covered 6 acres; and the building for the amateurs' exhibition and museum, 0.8 of an acre; giving a total floor-area for these chief buildings of nearly 37 acres. This is exclusive of several buildings and of the covered courts.

The official maps and lists of buildings in the three zones of the exhibition-area enumerated no less than 185 separate constructions, many of them of a costly character, erected as types of the architecture of the different nations. Besides these, there were the permanent attractions of the adjoining "Wurstel," or People's Prater, outside of the gates, numbering 103 buildings, chiefly restaurants and places of amusement. To the E. of the chief enclosure of the exhibition there was an almost unlimited space of open ground, where the exhibitions of cattle and horses, and the races, were held.

The façades of the Industry Palace and of the Art Buildings, as well as several smaller constructions, were elegantly decorated by cornices and bas-reliefs of stucco formed of plaster or cement, and colored to resemble stone. The floors of all the buildings were of wood, with narrow spaces left between the planks for the dust to fall through. The main entrances were at the S. and W. The access was chiefly by carriages, horse-railways, and omnibuses, but was not by any means adequate, and was never equal to emergencies, such as storms or special attractions drawing a larger crowd than usual.

The regulations and details of the conduct of the exhibition were early made known to the world by a series of carefully prepared circulars, numbered from 1 to 104, and onward. These were printed in German, English, and French in quarto form, and they give a very complete view of the organization and progress of the undertaking. Among these are several upon special industries or features of the exhibition, giving very comprehensive views of the condition and needs of those industries.

The classification comprised twenty-six groups, with numerous subdivisions. The arrangement of the objects did not follow the sequence of the groups. It was not systematic, and it was unsatisfactory. The space was apportioned "in block" to each country, and the placing or installation of the objects was left to the convenience or caprice of each of the foreign commissions. A geographical order of succession of the countries was adopted, the Eastern nations taking space at the eastern ends of the buildings, and the Western nations at the western ends. Japan thus occupied one end, and the U. S. the other end, while Prussia and Austria occupied the central portions.

Regret was very generally expressed, not only by the commissioners and jurors, but by the visitors and exhibitors, that the dual system of arrangement introduced in the Paris Exhibition of 1867 had not been adopted at Vienna. By this system, as is well known, similar objects from different countries are placed together, while at the same time the grouping by countries is preserved. Such an arrangement greatly facilitates study and comparison, and consequently promotes one great object of exhibitions—education. It saves a great deal of time and confusion, and makes the labors of jurors and experts much more satisfactory. In Vienna it was extremely difficult to find all the objects of any one group or class, and the direct comparison of such objects was impossible. The form of the building rendered such a systematic arrangement impracticable, and the only approximation to it was placing the machinery in one building, the agricultural implements in another, manufactures and products in a third, and fine arts in a fourth.

The display in all departments was very large and costly, and exceeded that in Paris in 1867. The aggregate weight and number of objects, and the outlay for show-cases and decorations, were much greater. The number of exhibitors is stated at 70,000.

The exhibition was particularly rich in the educational appliances and statistics of all countries, special attention to the subject having been requested in the official programmes. The collections so brought together are to remain in a special museum at Vienna. The several departments of government of the Austro-Hungarian monarchy made extensive and instructive exhibitions, particularly in forestry, mining, and commerce. The special exhibitions in Group I. (mining, metallurgy, etc.) by Prussia, Carinthia, and other countries, were remarkable for the thorough representation of those industries in a liberal and costly way. Japan made a very complete and creditable exhibition, giving a better representation of the arts and industries and resources of that empire than has ever before been seen. The machinery and agricultural implements from the U. S. were very creditable, and attracted much attention, but in these and in other departments the representation was by no means commensurate with the extent and resources of the country.

The international jury consisted of about 600 members from all countries, appointed by each commission in the general ratio of one juror for every 100 exhibitors in each group. The officers of the jury were apportioned among the nations by the imperial commission. The jury-work commenced in July, and the announcement of the awards was made in August. These awards were not internationally comparative, but were absolute, and were liberally bestowed. The medals were all of bronze, and of the same size, each seven centimètres in diameter, but of five different kinds, though not in gradation of merit or value; namely, 1, medal for fine arts; 2, medal for good taste; 3, medal for progress; 4, medal for co-operators; 5, medal for merit. The medal for *fine arts* was reserved for distinguished art productions exhibited in Group XXV. The medal for *good taste* was designed for exhibitors of articles of industry, the form and color of which constitute the characteristic features for adjudication. The medal for *progress* was given to exhibitors in Groups I. to XXIII., and in Group XXVI., who, compared with the productions exhibited at previous exhibitions, proved noticeable progress made since then in new inventions, in the introduction of new materials and contrivances, etc. The medal for *co-operators* was designated for persons who, as managers of manufactories, as foremen, designers of patterns, modellers, or as assistants in a general way, were nominated on the part of the exhibitors on account of the leading part they had taken in the features of excellence of the productions or in the increase of their sale. It shows on the reverse side a mechanic examining the parts of a machine which his aspiring assistant has just finished, and for the completion of which, as an acknowledgment, the Genius of Labor presents him with a laurel wreath. The medal of *merit* was awarded to exhibitors who could lay claim to excellence and perfection in material and workmanship, large extent of production, the opening of new markets, the employment of improved tools and machinery, and cheapness of production. There were also diplomas of merit and of honor, the latter having the character of a peculiar distinction for eminent merit in the domain of science and its applications.

A succession of international congresses during the progress of the exhibition was a marked feature, and contributed to its interest and good results. The Medical Congress, the Congress on a Uniform Numbering of Yarn, the Flax Congress, and the International Patent Congress were among the most important. The latter was well attended, and resulted in the formation of a permanent international executive committee under the presidency of Baron Schwarz-Senborn, with power to enroll members and call another meeting in 1876 or before.

From the opening until November 3 there were 7,254,687 visitors or entries recorded by the turnstiles. This number includes all, whether paying or free, and of course does

not represent different persons, each visit of the same person counting one. This number is equivalent to about 20 per cent. of the population of Austria. The visitors in London in 1862 were equal to about 20 per cent. of the population of Great Britain.

There were several concurrent unfavorable conditions tending to prevent a large influx of visitors. In the first place, the exhibition was not fairly ready to receive visitors until after the first of June. The month of May was cold and rainy, and the first impression produced on the public was unfavorable. The press also was in a critical mood, and the vexations and fatigue attending a study of the exhibition disgusted those who arrived with the expectation of being satisfied without effort. Later in the season the presence of cholera to a limited extent sufficed to keep away many tourists who had deferred their visits. The sovereigns of Europe visited the exhibition in succession. Delegations of artisans were sent by Switzerland and other nations. The free list was large, including all the foreign commissioners, jurors, and exhibitors.

The receipts were much less than was expected, being only about 2,600,000 florins (or $1,300,000) from visitors, as far as ascertained at the closing; but this does not represent all, as the full reports had not been received from the railways. There were in addition certain revenues from the rent of space, each country paying a small sum per square mètre, and from the concessions. The buildings are also to be sold. But the gross revenues will probably not exceed $2,000,000 in round numbers, while the expenditures are reported as equivalent to $9,850,000, leaving a deficiency of $7,850,000, already mostly provided for by government appropriations. WM. P. BLAKE.

Ex post Fact'o, a legal term introduced from the civil to the common law. Its literal translation is, "by subsequent matter," or "in consequence of something done afterwards." An *ex post facto* law is a law that operates by after-enactments. By the Constitution of the U. S., neither Congress nor the State legislatures can pass *ex post facto* laws, and the meaning of the term thus used has been often defined and is fully settled by judicial decisions. It refers to criminal and penal statutes only, and not to those which simply affect private property. Chief-Justice Marshall defined an *ex post facto* law to be one which rendered an act punishable in a manner in which it was not punishable when it was committed. The more specific definition usually laid down by the courts is: 1, any law which makes an innocent act, done before its passage, criminal; 2, any law which aggravates a crime, and makes it legally greater than when it was committed; 3, any law which changes the punishment, and inflicts a greater punishment than the law affixed to the crime when it was committed, or perhaps one different in kind; 4, any law that alters the legal rules of evidence applicable to an offence already committed, and to the injury of the offender.

Express' [from the Lat. *ex*, "out," and *premo, pressum*, to "press," to "urge"]. This word, originally applied to a messenger sent on pressing or special service, has by popular usage in the U. S. become confined in its meaning, and is employed to designate the business of taking special charge of packages of any description and forwarding them to their destination. This business has grown directly out of the wants of the community: it stands midway between the post-office system of conveyance and the ordinary method of freighting goods by railroad or steamboat. Compared with the post-office, which carries mail matter at the risk of the owners, the express offers at least equally prompt deliveries, and, further, guarantees them; a company or firm assuming responsibility for the packages entrusted to its care. Hence, the express is employed in preference to carry packages of value. With regard to the comparative cost of transmission, packages exceeding a certain weight (varying chiefly with the distance to which they are to be sent, since that, more than anything else, determines the express charges) cannot be sent as cheaply by post as by express. But for small parcels the postal charge is much less than that of the express, and very recent changes (Jan. 1, 1875), which it is feared may considerably diminish the revenues of express companies from this class of business, have largely extended the limit, at low rates, of the weight of packages that can be preferably sent by mail. This feature of the post-office system is, however, offset in some degree by the restrictions on low-rate mail matter, such as requiring it to be sent in wrappers with the ends open. Compared with the ordinary methods of freighting merchandise, the express system affords, aside from advantages of security of carriage and delivery, a more rapid conveyance. Instead of the slow movement by freight-trains on railroads, expresses engage at heavy cost space for the goods entrusted to them on passenger-trains. Between the great cities one or two cars on each passenger-train are solely devoted to this use, and on the less important routes a part of the baggage-car is thus engaged. An employé of the express, called an "express agent," invariably goes with the goods on the train. As the express system extends through 60,000 miles of railroads in the U. S., it is estimated that express agents travel 300,000 miles per day, and that individuals among them go over a space equal to the circuit of the globe six times in the year. The early expresses (1833) were established by newspapers to obtain prompt news. In 1839, Wm. F. Harnden first made a special business of carrying parcels between Boston and New York; the next year P. B. Burke and Alvan Adams started a competing express, and W. B. Dinsmore came into the business, which in 1841 extended to Philadelphia. Rapid progress was afterwards made in starting expresses, the first W. of Buffalo being that of Wells, Fargo & Dunning in 1845. The consolidation of many individual concerns into stock-companies began in 1850 with the formation of the American, followed in 1854 by the Adams, and afterwards by the United States, the National, Wells, Fargo & Co.'s, the Southern, and other express companies. The stock of four of these is represented by nearly $40,000,000 capital. There are 20,000 men wholly, and at least 30,000 more partly, employed in the express business. Its revenues exceed those of the post-office. One of its largest branches is the conveyance of bank-notes, which under the present paper-money system reaches vast dimensions; another is the collection of bills on the delivery of goods, which has created an important division of mercantile business that dispenses with the risks of credit. In Europe the express system is principally confined to the carriage and delivery of parcels in cities. (For the legal aspects of the express business see CARRIERS, COMMON.) WILLIAM C. WYCKOFF.

Ex'tra, a township of Ashley co., Ark. Pop. 603.

Ex'tract [Lat. *extractum*, from *ex*, "out," and *traho, tractum*, to "draw"], in pharmacy, is a name given to any solid substance (called simply an extract) or to a liquid substance (fluid extract) made by evaporating solutions containing medicinal principles, chiefly of vegetable origin. These solutions are made (1) by expressing the juices of fresh plants, or of dried ones after maceration, by means of hydraulic or other presses; (2) by means of liquid solvents, as water, alcohol, or ether, from which result "aqueous," "alcoholic," and "ethereal" extracts. These various methods are employed, some extracts being better prepared by one and some by another process. Sometimes the menstruum is allowed slowly to percolate and repercolate through the powdered drug, the solvent being at last removed by evaporation or distillation. Evaporation is frequently carried on *in vacuo* with great advantage, for a high degree of heat is injurious to many vegetable principles.

Extract of Meat [Lat. *extractum carnis*] is a preparation of beef, and sometimes of mutton, or of both combined, in which the muscular fibre, fat, and gelatine are removed, and the highly nitrogenous elements preserved and condensed into a semi-solid mass of about the consistence of ordinary butter. Commercial extract of beef is prepared on a large scale in the Argentine Republic, in Texas, and in other countries. Most of what is sold in Europe and the U. S. comes from Buenos Ayres, where its manufacture was first established under the supervision of the chemist Liebig. One establishment at Fray Bentos slaughters 400 oxen daily. In general, the finely cut beef is allowed to stand for a few hours in cold water; the liquid is then boiled for a time, and afterwards evaporated in a vacuum-pan. In some places the mincemeat is steamed, and the resulting liquids evaporated on rapidly revolving steel plates. In other establishments superheated steam is employed under pressure; the material is then submitted to powerful hydraulic compression, and the expressed liquid partially dried *in vacuo*.

Extract of meat is of variable quality and composition, and at the best but imperfectly represents the beef it was made from. Nevertheless, it is useful in preparing soups, and especially in nourishing those who are sick of low fevers, pyæmia, and other like diseases.

Extraction of Roots. See EVOLUTION.

Extradi'tion [from the Lat. *ex*, "out," and *trado, traditum*, to "convey"], the surrender by one state or nation to another of fugitives from justice. The subject will be considered under two general divisions: 1, the surrender of fugitives from justice from one State of the U. S. to another; 2, the like surrender as between one nation and another.

1. The U. S. Constitution provides that "a person charged in any State with treason, felony, or other crime, who shall flee from justice and be found in another State,

shall, on demand of the executive authority of the State from which he fled, be delivered up to be removed to the State having jurisdiction of the crime." A like clause is found in the Articles of Confederation. The propriety and necessity of such a provision in the case of States bound so closely together as are those of the American Union, and yet exercising independent criminal jurisdiction, will not be questioned. It tends to promote harmony between the States and to repress crime, while it aids in the discharge of a high moral obligation. An act of Congress of 12th Feb., 1793, ch. 7, § 1, carries the constitutional provision into practical effect by declaring that the demand shall be accompanied by a copy of an indictment found against the alleged fugitive, or by an affidavit made before a magistrate of a State, etc., charging the fugitive with having committed a crime. These documents are to be certified as authentic by the governor or chief magistrate of the State whence the demand comes. It is thereupon made the duty of the governor on whom the demand is made to issue his warrant and to cause the fugitive to be arrested and delivered over to the agent of the demanding State. The essential ingredients of the case are—that there must be a charge that an act has been committed which is a crime under the laws of the State where it took place, and that the person so charged has fled from justice. The governor of the State where the fugitive is found is bound to comply with the demand when properly made and authenticated. Still, there are no legal means whereby, in case that he fails to do his duty, he can be compelled to perform it. (*Kentucky against Governor Dennison of Ohio*, 24 Howard's Reports, 66.) If the fugitive is supposed to be arrested on insufficient papers, the regular course to test their validity in his behalf is to apply for a writ of *habeas corpus*. If they turn out to be defective, he will be discharged. When the proceedings are sustained, the effect of them is to return the fugitive to the State whence he came, where he will be entitled to his trial under the ordinary course of judicial proceedings.

2. Extradition as between separate nations. This is a topic belonging to international law, and will be noticed under that general subject. It was at one time supposed that it was the duty of a state under the law of nations to surrender up a fugitive from justice upon demand after the civil magistrate had ascertained the existence of reasonable grounds for subjecting the accused to a criminal trial. Those who maintained this doctrine found much difficulty in drawing the line between the graver crimes to which it was claimed that this rule was applicable and those of a minor character to which it could scarcely be considered that it would extend. (1 Kent's "Commentaries," 37.) The better opinion now is, that whatever obligation may exist in such a case is an imperfect one, and cannot be insisted upon by the demanding nation unless there be a treaty stipulation. It is quite clear that courts have no power in such cases independent of treaties, and it is a matter of grave doubt whether the executive authority can properly exercise it. So a State of the Union cannot assume to make a surrender of an alleged fugitive to a foreign nation, and an act of a State legislature authorizing it is unconstitutional and void. (*People against Curtis*, 50 New York Reports, 321, A. D. 1872.) The U. S. have treaties upon this subject with a large number of foreign nations, including Great Britain, France, Austria, the German empire, Norway, Sweden, Italy, Switzerland, Mexico, etc. The treaties are not precisely identical, though of the same general scope and character. They all include the more heinous crimes, such as murder and piracy, while some of them embrace robbery, burglary, arson, rape, embezzlement, and the fabrication and circulation of counterfeit coin or paper. The words here employed would refer to the offences named as understood in the general jurisprudence of the two nations, and accordingly would not extend to a new statutory crime established by one of the States of this country, and called by a name used in the treaty, such as forgery. This conclusion was reached in England in the case of Winsor, 6 Best & Smith's Reports, 522. On the other hand, it has been considered that the word "piracy," as used in the treaty with England, does not refer to that offence as recognized in the law of nations, as the offender can be tried in the state where he is. Its reference is to piracy under the municipal law of the state making the demand. (*In re Tivnan*, 5 Best & Smith, 645.) The treaties require that the offence should be committed within the "jurisdiction" or within the "territories and jurisdiction" of the demanding nation. An interesting question has recently arisen in this country whether these words would include the case where a nation by statute law made it a crime for one of its own subjects to commit an act like murder beyond its own territory, so that a surrender could be demanded by that nation, though the act were committed within the territory of a nation with which the U. S. had no extradition treaty. This was the case of Vogt, and though the attorney-general of the U. S. advised against the surrender, the point can scarcely be deemed to be finally settled. In order to carry an extradition treaty into practical effect, domestic legislation is necessary. Under the laws of Congress and the practice of the courts the following points must be observed: (1) There must be a demand from the supreme political authority of the state seeking the return of the fugitive; (2) There should be an authorization or a mandate by the President of the U. S., directed to a judge or U. S. commissioner, to examine into the case; (3) Complaint under oath should be made to the judge or commissioner by a proper person, such as a consul-general of the foreign country, showing the commission of the act on which the demand for the surrender is based; (4) There should be a warrant by the commissioner, etc. for the apprehension of the party charged; (5) The charge should be sustained before the commissioner by suitable evidence, such, for example, as would justify his commitment had the act taken place here; (6) On the certificate of the judge or commissioner that there is a probable ground to believe that the offence has been committed, and such certificate is satisfactory to the President of the U. S., the surrender is made to the agent of the demanding state. If the proceedings are defective, the prisoner may be discharged on a writ of *habeas corpus*. The statutes will be found in 9 U. S. Stat. at Large, 302 (12 Aug., 1848); 12 id., 84 (22 June, 1860); 15 id., 337 (Mar. 3, 1869). Consult also *Matter of Farez*, 7 Blatchford Reports, 345, 491; BRIGHTLY'S and ABBOTT'S "Digests," title *Extradition;* WHEATON'S "International Law," notes of LAWRENCE and DANA; CLARKE "On Extradition," etc.; the recent English statutes, 33 & 34 Vict. ch. 52 (1870); 36 & 37 Vict. ch. 60 (1873). T. W. DWIGHT.

Extreme Unction [Lat. *extrema unctio*, the "last anointing"], the fifth of the seven sacraments of the Roman Catholic Church, consisting of the application, by a priest, of consecrated oil of olives to the eyes, ears, nostrils, lips, hands, feet, and reins of a dying person or of one whose illness is alarming. It is administered after confession and the Eucharist, and is believed to remove the last stains of sin. The Greek and Coptic churches recognize unction (which is by no means always administered *in extremis*) as a sacrament, and the Jacobites and Armenians have a similar practice. Certain ritualists among the Anglicans and Lutherans advocate a return to this ceremony.

Exuda'tion [Lat. *exudatio*, from *ex*, "out," and *sudo*, *sudatum*, to "sweat"], the passage of a liquid outward through the walls (or membranes) of the vessel containing it. The term is also applied to certain substances which *exude* or come out of trees, as gum-resin, manna, etc. In pathology, a material product of inflammation; a gaseous, liquid, or solid substance foreign to the tissues, and resulting from disease. These morbid products, when solid, sometimes become organized and capable of growth.

Exu'ma, Great and **Little,** two of the Bahama Islands. The former is about 30 miles long and 3 miles wide, and has one of the best harbors in the Bahamas. Salt is exported from them. Great Exuma is crossed by the Tropic of Cancer. The N. W. point is in lat. 23° 42′ N., lon. 76° W.

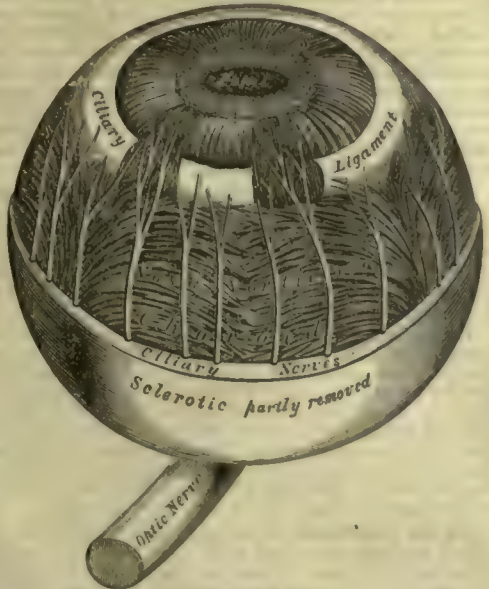
Exu'viæ (plu.), [Lat. for "cast-off clothing"], in natural history, the name for the slough or cast-off skin of reptiles, crustaceans, etc.; the moulted feathers of birds; the hair of quadrupeds, which is shed at a particular season of the year. It is sometimes a general name for fossil organic remains. It was anciently used to designate the personal spoils taken from an enemy in battle, hence it sometimes meant all booty taken in war.

Eyck, van (HUBERT and JAN), two brothers, born at Maaseyk, Holland—Hubert in 1366, Jan about four years later. They lived and wrought as artists together. Their chief works were executed in Ghent. The two brothers are considered the founders of the Flemish school of painting. (An account of their labors, with an estimate of their merits and a just assignment of their place in art, may be found in a book on "Early Flemish Painters" by CAVALCASELLE, London, 1856, and in DR. LÜBKE'S "History of Art," translated by F. E. BUNNETT, London, 1868; STANLEY'S "Dutch and Flemish Painters," Bohn's ed.) Jan died in 1440, Hubert in 1426. The former is often called "John of Bruges."

Eye, a market-town of England, is in the county of Suffolk, 75 miles N. E. of London. The houses are low, with thatched roofs, and the streets unpaved. Pop. 6721.

Eye, the organ of vision in animals. In organisms below the rank of the Echinodermata eyes can scarcely be said to exist, but among star-fishes and Echinida eye-spots

connected with nerve-filaments are found. Among the lowest articulates rudimentary eyes are seen, not always on the head, but on various parts of the body, and sometimes even at the end of the tail. In tunicaries and true mollusks vision exists, sometimes performed by means of eyes of considerably high development. Most of the high articulates have compound eyes. Insects have large eyes, each with a vast number of hexagonal or quadrangular doubly convex facets, every one of which brings to a focus the rays received in one particular direction. In the *Mordella* beetle the eyes have 25,000 of these facets or corneas (*Carpenter*), but the number is usually very much less. Faceted eyes are common among crustaceans, and are often well marked in the remains of trilobites. Spiders and others of the lower insects have only a few eyes, which are not compound. Many facet-eyed insects have also single rudimentary eyes.



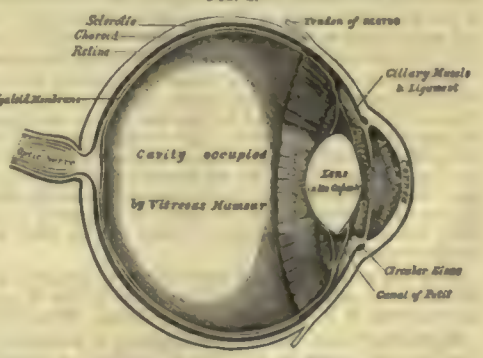
The vertebrates nearly all have eyes which approximate more or less completely to those of man, some, as the birds, probably far surpassing man in visual power. The eye of fishes and cetaceans is peculiar in its spherical and dense crystalline lens. There are many other special modifications in the eyes of lower animals, adapting them to their peculiar modes of life.

The human eye is placed in a bony cavity called the orbit, and is further protected by the fatty cushion within which it rests, as well as by the brows, eyelids, and eyelashes. Other appendages are the tear-glands and the sac connected with it; the Meibomian glands, whose secretion lubricates the eyelids and the eye itself; the numerous muscles which direct its range, and the nerves and blood-vessels which supply it.

The human eye is a globe, with the segment of a smaller globe planted upon its anterior aspect. Its antero-posterior diameter is one inch, its transverse one, $\frac{1}{12}$ of an inch. The larger sphere has about five-sixths of the whole surface. The two eyes have their axes almost parallel, except that in looking at near objects they decidedly converge. The eye is invested by three coats: First, the sclerotica, a white, tough, fibrous substance, the "white of the eye," visible through the delicate conjunctiva which lines the orbit and is reflected over the sclerotica and cornea. Inwardly it is brown. The muscles are attached to it, and through a sieve-like, "cribriform lamina" it transmits the filaments of the optic and other nerves and blood-vessels.

The anterior one-sixth of the eye's surface is occupied by the cornea, a concavo-convex lens, projecting, transparent, and in intimate structure resembling the sclerotica. It is composed of more than sixty laminæ, the innermost and outermost of which are highly elastic. The posterior layer is lined by a "pavement" epithelium of polygonal cells. The cornea is well supplied with nerves, called *ciliary*.

Fig. 1.



Choroid and Iris.

The second coat of the eye is composed of the choroid tunic, the iris, the ciliary processes, muscle, and ligament. The choroid is a vascular, thin, chocolate-colored membrane, lining the sclerotica, and separated from it by the delicate membrana fusca. The choroid itself has three layers: an *outer*, consisting chiefly of blood-vessels (vasa vorticosa) and pigment-cells; a *middle* layer, of fine capillary vessels (Ruysch's layer); and an *inner* layer, of tesselated, hexagonal cells, laden with pigmentary matter, except in albinoes. The ciliary processes are folds or plaits running forward from the edge of the choroid to the suspensory ligament of the crystalline lens. They number about 70. The iris ("rainbow") takes its name from its various colors in different persons. It is the colored curtain which surrounds the pupil, its central opening. It contains both circular and radiating involuntary muscle fibres – the circular to contract, the radiating to expand, the pupil. The ciliary ligament unites the choroid and cornea. The circular sinus is a canal which runs around the eye outside the ciliary ligament. The ciliary muscle is a circular band of involuntary muscle-fibre which passes back from the junction of the cornea and sclerotic to the choroid. It is probable that through the ciliary processes it acts upon the lens, adjusting the eye for nice observations.

The third coat of the eye is the retina. Without is the choroid—within, the vitreous humor. The retina has four layers. The *outer*, or Jacob's membrane, consists of columnar rods and bulbous, hollow cones filled with fluid. The *granular* layer consists of globular particles, lined inwardly by a hyaline substance. The *nummular* layer looks on the inside as if composed of particles resembling pieces of money seen edgewise. The *nervous* layer of the retina is an expansion of the optic nerve, and consists of both tubular and vesicular neurine. This layer is separated within from the vitreous humor by the exceedingly delicate membrana limitans, and by the hyaloid membrane; the former regarded as belonging to the retina, the latter to the vitreous humor.

The contents of the eye are the aqueous humor, the crystalline lens, and the vitreous humor. The aqueous humor consists of about four or five grains of water, with a very small proportion of common salt and others matters in solution. It occupies the space between the cornea in front and the crystalline lens behind. This space is divided into the anterior and the posterior chambers, which the iris separates from each other. After birth these chambers communicate through the pupil. (Fig. 2, Vertical section of the human eye.) Behind the aqueous humor comes the

Fig. 2.

Vertical Section of the Eye.

crystalline lens, suspended in the capsule, an elastic, transparent membrane which is retained in place by the ciliary processes and a suspensory ligament. Between this ligament and the hyaloid membrane is the space called the canal of Petit. The lens itself consists, as is seen when it has been boiled or hardened in alcohol, of layers of transparent matter arranged in three triangular segments. The vitreous humor occupies four-fifths of the cavity of the eyeball. Like all the contents proper of the eye, it is transparent. It consists of a thin, jelly-like, albuminous fluid. When the aqueous humor has been evacuated by accident or operative interference, it is speedily restored like other serous fluids, but if the vitreous humor is once lost, it is never renewed.

(The wonderful physiology and physics of the eye, its nice self-adjusting powers, and its almost perfect achromatism are considered in the articles Light and Vision. The various diseases of the eye are treated each under its own name.)

Charles W. Greene.

Eye-Bolt, on shipboard, a pointed iron bar with a hole in the thick end. It is intended to be driven into one of the timbers, and then to have a rope passed through the hole.

Eyebright. See Euphrasy.

Eye-Piece, the lens or combination of lenses used in microscopes and telescopes to examine the aërial image formed at the focus of the object-glass. The ordinary eye-piece is a combination, and may be either positive or negative.

The former consists of two plano-convex lenses, with their convex sides towards each other, and is used for micrometers. The negative consists of similar lenses with the convex sides turned away from the eye. Besides these, there are in use for observations of the sun a diagonal eye-piece, in which a very small percentage of the sun's light and heat is reflected from the first surface of a prism, the rest being transmitted; and Dawes's solar eye-piece, in which the light is reduced by observing only a very minute part of the solar surface.

Eye-Stones (*oculi cancrorum*) is the name given to the two semi-circular calcareous concretions which are found in the common European crawfish, in August, shortly before the moulting season, in the space between the inner and outer coats of the stomach. They consist of carbonate and phosphate of lime and animal gelatin, and were formerly used in a powdered state in medicine as an antacid. They are sometimes used to remove small particles of dirt from the eyes, a method which is entirely to be condemned. They are collected in brooks in Dauphiny, near Astrakhan, etc.

Eye, von (Johann Ludolf August), a German art-historian, born 1825, wrote many valuable works on ancient and modern art. Among these are "Kunst und Leben der Vorzeit" (3 vols., 3d ed. 1868), "Leben und Wirken Albrecht Dürer's" (1860). He also wrote several philosophical works, the most prominent of which is "Wesen und Werth des Dascins" (1870).

Eylau, or **Eilau,** ī'lŏw', often called **Prussian Eylau,** a small town of Prussia, is in the province of Prussia, on the Pasmar, 22 miles S. of Königsberg. A great battle was fought here Feb. 8, 1807, between Napoleon, who had about 80,000 men, and the allied armies of Russia and Prussia, commanded by Gen. Bennigsen, who had fewer men, but more guns. Both sides claimed the victory. The allies lost about 20,000, and retreated from the field, but the French loss was probably the greater. Pop. in 1867, 3518.

Ey'lert (Ruhlemann Friedrich), born at Hamm, Westphalia, April 5, 1770, studied at Halle, and in 1794 began to preach in his native town, became court-preacher at Potsdam in 1806, and in 1817 Prussian superintendent and minister of public instruction. He was at first a moderate rationalist, but became orthodox, and was one of the founders of the national Church of Prussia and of its liturgy. He had great influence with King Frederick William III. Died Feb. 3, 1852, leaving numerous writings, chiefly religious.

Ey'meric (Nicholas), a famous inquisitor, born at Girona, a town of Catalonia, Spain, became a Dominican friar in 1334, was appointed by Innocent VI. to be inquisitor-general of Aragon (1356), and became chaplain and judge of heresies to Gregory XI. at Avignon (1371). Died at Girona Jan. 4, 1399. As an inquisitor his zeal was so great that he was for some years suspended from his office. He especially pursued the followers of Raymond Lully. His "Directorium Inquisitorum" (1503; 6th ed. 1607) was his principal work.

Eyo'ta, a township and post-village of Olmstead co., Minn., has a monthly publication. It is on the Winona and St. Peter R. R., 37 miles W. of Winona. Pop. 1140.

Eyre (Most Rev. Charles), archbishop of Anazarba *in partibus,* and apostolic delegate of the Roman Catholic Church for Scotland, was born in 1817 in Yorkshire, England, and was educated at Durham and at Rome. He received his present position in 1869. He has published a "History of Saint Cuthbert" (1849).

Eyre (Edward John), an English explorer, born in 1817. He emigrated to Australia about 1833, and began in 1840 the exploration of the unknown region between South Australia and Western Australia. In this sterile region he performed a journey of nearly 1000 miles almost alone. He published in 1845 "Discoveries in Central Australia." In 1862 he was appointed governor of Jamaica, where he suppressed an insurrection in Oct., 1865. He was censured and removed from his office for the execution of Gordon by court-martial. John Stuart Mill and others took measures to try him for murder, but failed, Eyre being justified or excused by the British public.

Eyre (John), an Anglican clergyman, born at Bodmin, Cornwall, in Jan., 1754, was apprenticed to a clothier, but, having become awakened to a religious life, was driven from his father's house. He went to Lady Huntingdon's college at Trevecca, studied for a time at Oxford, and soon entered the ministry. He was a popular speaker, and was chiefly distinguished for his benevolence and zeal for missions. He was one of the founders of the London Missionary Society and of Hackney Seminary. Died Mar. 28, 1803.

Eyre (Sir Vincent), K. C. S. I., C. B., born about 1810, received a military education in the college of Addiscombe, joined the Bengal artillery in 1828, was badly wounded at Cabul in 1842, while serving in the horse artillery, and was taken prisoner by the Afghans, but escaped in Sept., 1842. He has published "Military Operations at Cabul" (1843), "Metallic Boats and Floating Wagons" (1854), and "A Fortnight's Tour among French Ambulances" (1870).

Eyriès (Jean Baptiste Benoît), a French savant, born in Marseilles, published numerous geographical papers, mostly translations, wrote much for the "Biographie Universelle," and, with John Pinkerton, published an "Abridgment of Modern Geography" (1827), a work of value in its day. He was one of the originators of the Geographical Society. Died in 1846.

Eys'ter (Michael), an American Lutheran minister, was born May 16, 1814, in York co., Pa., was educated at Gettysburg, and licensed to preach in 1838. His influence as a pulpit orator was very great. Died Aug. 12, 1853.

Ey'telwein (Johann Albert), an excellent Prussian civil engineer and physicist, born at Frankfort-on-the-Main Dec. 31, 1764, entered the artillery in his youth, where he acquired the foundation of his future eminence. He afterwards held important civil offices, and was employed on a great variety of public works. Died Aug. 18, 1848. He published a "Handbook of Mechanics, of Solids, and of Hydraulics" (1801), "Handbook of the Statics of Solid Bodies" (1808), "Handbook of Perspective" (1810), "Elements of the Higher Analysis" (1824), etc.

Eze'kiel (*i. e.* "God will strengthen"), one of the four greater prophets of the Hebrew Scriptures, the author of a canonical book which bears his name. He was the son of a priest, and was one of those who were carried away in what is known as the second of the four deportations (597 B. C.). He was sent to dwell on the river Chebar or Chaboras, a branch of the Euphrates. From that place he exercised his prophetical calling by pronouncing warnings and rebukes against Jerusalem so long as it stood, and also by denouncing woes upon Judah's heathen neighbors for their attitude towards her in her distress. His activity covered a period of twenty-two years, from the fifth to the twenty-seventh year of the Captivity. The book consists of two parts, the former (chaps. i.–xxiv.) containing predictions delivered before the destruction of Jerusalem in 586 B. C.; the latter (chaps. xxv.–xlviii.) containing predictions delivered after that event. Having formed an ideal of what the restored Israel was to be, he describes the new temple, the reformed ritual, and a re-division of the country into twelve parts, which is set forth in mathematical and geometrical descriptions. These descriptions do not apply to anything which ever existed, either before or after, and this has been a ground of much unfounded anxiety lest here should be an unfulfilled prophecy. It is evident, however, that the prophet had a vision of a restored, perfect, and ideal theocracy, and this is set forth in mathematical and geometrical arrangements which are ideally perfect, and take no note of physical circumstances. In his general tone Ezekiel is independent of Jewish dogmas. He gives fresh and true interpretations and applications of the Mosaic law, which contradict the traditional interpretations. His view of the Gentiles is also free from the severity of the traditional dogma of Israel's election. Fürst finds authority in the "Talmud" for the assertion that, on account of these things, the position of the book of Ezekiel in the canon was uncertain at the time of our Lord.

E'zion-ge'ber, or **Ezion-gaber,** an ancient port on the Elanitic arm of the Red Sea. From this point Solomon sent a fleet to Ophir, and King Jehoshaphat also built ships here for the same destination. It probably stood near Elath, and is thought by many to have been at the north-western extremity of the Gulf of Akabah. It is believed that no trace of it now remains.

Ez'ra [Heb. "help;" Gr. Ἔσδρας], the name of several persons mentioned in the Bible, the most important of whom was the famous priest and scribe who came with some 6000 Hebrew exiles from Babylon to Jerusalem about the year 458 B. C. In no long time, probably, he went back to Babylon, and returned to Jerusalem with Nehemiah in 445 B. C. As he is not mentioned after Nehemiah's return to Babylon in 433 B. C., he had probably died, or gone back to Babylon, before this. His reputed sepulchre is shown at a place on the Tigris, near its junction with the Euphrates.

Ez'ra, The Book of, called in the Thirty-nine Articles of the Anglican Church "The First Book of Esdras," following the Vulgate. It narrates the history of the Jewish nation on their return to Jerusalem from the Babylonian captivity, and during the subsequent period of their re-establishment in the land of their fathers. It is a continuation of the books of Chronicles, and is mostly a compilation, probably by Ezra, who, though he put the whole together, himself wrote only the last four chapters. It is written partly in Hebrew and partly in Chaldee, the Chaldee portion beginning at iv. 8 and extending to vi. 18.
